ROYAL COMMISSION ON SEWAGE DISPOSAL.

INTERIM REPORT

OF

THE COMMISSIONERS

APPOINTED IN 1898

TO INQUIRE AND REPORT WHAT METHODS OF

TREATING AND DISPOSING OF SEWAGE

(Including any Liquid from any Factory or Manufacturing Process)

MAY PROPERLY BE ADOPTED.

Presented to both Houses of Parliament by Command of His Majesty.

VICTORIA R.

Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith: To Our Right Trusty and Right Well-beloved Cousin, Walter Stafford, Earl of Iddesleigh, Companion of Our Most Honourable Order of the Bath; Our Trusty and Well-beloved Sir Richard Thorne Thorne, Knight Commander of Our Most Honourable Order of the Bath, Medical Officer of the Local Government Board; Our Trusty and Well-beloved Constantine Phipps Carey, Esquire, Lieutenant-Colonel and Honorary Major-General on the Retired List of Our Army; Our Trusty and Well-beloved Charles Philip Cotton, Esquire; Our Trusty and Well-beloved Michael Foster, Esquire, Master of Arts, Professor of Physiology in Our University of Cambridge; Our Trusty and Well-beloved Thomas Walter Harding, Esquire, Retired Lieutenant-Colonel of Our Auxiliary Forces, with Honorary Rank of Colonel; Our Trusty and Well-beloved Thomas William Killick, Esquire; Our Trusty and Well-beloved William Ramsay, Esquire, Professor of Chemistry, University College, London; and Our Trusty and Well-beloved James Burn Russell, Esquire, Doctor of Medicine, Master of Surgery: Greeting!

Whereas We have deemed it expedient that a Commission should forthwith issue to inquire and report:

1. (1) What method or methods of treating and disposing of sewage (including any liquid from any factory, or manufacturing process) may properly be adopted, consistently with due regard for the requirements of the existing law, for the protection of the public health, and for the economical and efficient discharge of the duties of local authorities; and

   (2) If more than one method may be so adopted, by what rules, in relation to the nature or volume of sewage, or the population to be served, or other varying circumstances or requirements, should the particular method of treatment and disposal to be adopted be determined; and

2. To make any recommendations which may be deemed desirable with reference to the treatment and disposal of sewage;

Now know ye, that We, reposing great trust and confidence in your knowledge and ability, have authorised and appointed, and do by these Presents authorise and appoint, you, the said Walter Stafford, Earl of Iddesleigh, Sir Richard Thorne Thorne, Constantine Phipps Carey, Charles Philip Cotton, Michael Foster, Thomas Walter Harding, Thomas William Killick, William Ramsay, and James Burn Russell to be Our Commissioners for the purposes of the said Inquiry.

And, for the better effecting the purposes of this, Our Commission, We do by these Presents give and grant unto you, or any three or more of you,

full power to call before you such persons as you shall judge likely to afford you any information upon the subject of this Our Commission; and also to call for, have access to, and examine all such books, documents, registers, and records as may afford you the fullest information on the subject, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And We do by these Presents authorise and empower you, or any three or more of you, to visit and personally inspect such places as you may deem it expedient so to inspect for the more effectual carrying out of the purposes aforesaid.

And We do further by these Presents will and ordain that this Our Commission shall continue in full force and virtue, and that you, Our said Commissioners, or any three or more of you, may from time to time proceed in the execution thereof, and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

And we do further ordain that you, or any three or more of you, have liberty to report your proceedings under this Our Commission from time to time, if you shall judge it expedient so to do.

And Our further will and pleasure is that you do, with as little delay as possible, report to Us under your hands and seals, or under the hands and seals of any three or more of you, your opinion upon the matters herein submitted for your consideration.

And for the purpose of aiding you in such matters, We hereby appoint Our Trusty and Well-beloved Frederick James Willis, Esquire, to be Secretary to this Our Commission.

Given at Our Court at Saint James's, the Seventh day of May, One thousand eight hundred and ninety-eight, in the Sixty-first Year of Our Reign.

By Her Majesty's Command,

(Signed) M. W. Ridley.

William Henry Power, Esq., F.R.S.,

To be a Member of the Royal Commission on Sewage Disposal.

VICTORIA, R.

Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith: To Our Right Trusty and Well-beloved William Henry Power, Esquire, Fellow of the Royal Society, Medical Officer of the Local Government Board: Greeting!

Whereas We did, by Warrant under Our Royal Sign Manual, bearing date the Seventh day of May, One thousand eight hundred and ninety-eight, appoint Our Right Trusty and Right Well-beloved cousin Walter Stafford, Earl of Iddesleigh, Companion of Our Most Honourable Order of the Bath, together with the several Gentlemen therein mentioned, or any three or more of them, to inquire into the treatment and disposal of sewage.

And Whereas One of the Commissioners so appointed, namely, Sir Richard Thorne Thorne, has since deceased.

Now know Ye, that We, reposing great confidence in you, do, by these presents, appoint you, the said William Henry Power, to be one of Our Commissioners for the purpose aforesaid, in the room of the said Sir Richard Thorne Thorne, deceased, in addition to, and together with, the other Commissioners whom we have already appointed.

Given at our Court, at Saint James's, the Seventh day of February, One thousand nine hundred, in the Sixty-third Year of Our Reign.

By Her Majesty's Command,

(Signed) M. W. Ridley.

Whitehall, March 18th, 1901.

The King has been pleased to issue a Commission, under His Majesty's Royal Sign Manual, to the following effect:—

EDWARD, R.

Edward the Seventh, by the Grace of God, of the United Kingdom of Great Britain and Ireland King, Defender of the Faith, to all to whom these Presents shall come, Greeting!

Whereas it pleased Her late Majesty from time to time to issue Royal Commissions of Inquiry for various purposes therein specified:

And Whereas in the case of certain of these Commissions, namely, those known as—

The Historical Manuscripts Commission;
The Horse Breeding Commission;
The Local Taxation Commission;
The Port of London Commission;
The Salmon Fisheries Commission; and
The Sewage Disposal Commission;

the Commissioners appointed by Her late Majesty, or such of them as were then acting as Commissioners, were, at the late demise of the Crown, still engaged upon the business entrusted to them:

And whereas We deem it expedient that the said Commissioners should continue their labours in connection with the said inquiries notwithstanding the late demise of the Crown :

Now Know Ye, that We, reposing great trust and confidence in the zeal, discretion, and ability of the present members of each of the said Commissions, do by these Presents authorize them to continue their labours, and do hereby in every essential particular ratify and confirm the terms of the said several Commissions.

And We do further ordain that the said Commissioners do report to Us under their hands and seals, or under the hands and seals of such of their number as may be specified in the said Commissions respectively, their opinion upon the matters presented for their consideration ; and that any proceedings which they or any of them may have taken under and in pursuance of the said Commissions since the late demise of the Crown, and before the issue of these Presents shall be deemed and adjudged to have been taken under and in virtue of this Our Commission.

Given at Our Court at Saint James's, the fourth day of March, One thousand nine hundred and one, in the First Year of Our Reign.

By His Majesty's Command,

(Signed) Chas. T. Ritchie.

INTERIM REPORT.

TO THE KING'S MOST EXCELLENT MAJESTY.

MAY IT PLEASE YOUR MAJESTY,

We, the Commissioners appointed to inquire and report :—

I. (1) What method or methods of treating and disposing of sewage (including any liquid from any factory or manufacturing process) may properly be adopted, consistently with due regard for the requirements of the existing law, for the protection of public health, and for the economical and efficient discharge of the duties of Local Authorities ; and

(2) If more than one method may be so adopted, by what rules, in relation to the nature or volume of sewage, or the population to be served, or other varying circumstances or requirements, should the particular method of treatment and disposal to be adopted be determined ; and

II. To make any recommendations which may be deemed desirable with reference to the treatment and disposal of sewage.

Humbly report, as follows :—

PRELIMINARY.

1. We have examined a large number of witnesses, and visited many sewage works of various kinds. We have also instituted through our own officers a number of necessary scientific investigations.

2. Many of these investigations are still in progress, and considerable time must necessarily be taken by the work which still remains to be done, and especially by such work as is needed before the second part of the Terms of Reference can be adequately dealt with.

3. We have, however, arrived at conclusions on three questions which appear, for reasons hereafter given, to be of urgent importance, and we have therefore deemed it desirable to make a preliminary report and to publish the evidence already taken.

The three questions are :—

(1) Are some sorts of land unsuitable for the purification of sewage.

(2) Is it practicable uniformly to produce by artificial processes alone an effluent which shall not putrefy, and so create a nuisance in the stream into which it is discharged.

(3) What means should be adopted for securing the better protection of our rivers.

Conclusions of previous Commissions.

4. Mr. Alfred Douglas Adrian, C.B., who, as Assistant Secretary of the Local Government Board, had charge for some years of the department concerned with questions of sewerage and sewage disposal, was the first witness whom we examined. His evidence contains a most valuable historical statement of the subject of sewage disposal, of the law on the subject, and of the practice of the Local Government Board in regard to this matter.

5. The first Sewage Commission was appointed in the year 1857. In 1865, as a result of labours extending over eight years, they reported that :— Adrian, 35.

"The right way to dispose of town sewage is to apply it continuously to land, and it is only by such application that the pollution of rivers can be avoided." Adrian, 52.

Adrian, 56. 6. In 1868, a further Commission was appointed to inquire into the best means of preventing the pollution of rivers. They made several reports, the fifth and last being made in 1874.

Adrian, 61. The opinion of this Commission on the comparative merits of the three classes of processes for the treatment of sewage, viz. :—chemical precipitation, intermittent filtration, and broad irrigation, may be stated thus :—(1) All these processes are to a great extent successful in removing polluting organic matter in suspension. But intermittent filtration is best, broad irrigation ranks next, and the chemical precipitation processes are less efficient. (2) But for removing organic matters in solution the processes of downward intermittent filtration and broad irrigation are greatly superior to upward filtration and chemical processes.

Adrian, 71. 7. The last Commission was appointed in 1882. They were directed to inquire into and report upon the system under which sewage was discharged into the Thames by the Metropolitan Board of Works, whether any evil effects resulted therefrom, and, if so, what measures could be applied for remedying or preventing the same.

Adrian, 74. In November 1884 they issued their final Report. They found that evils did exist " imperatively demanding a prompt remedy," and that by chemical precipitation a certain part of the organic matter of the sewage would be removed. They reported, however, " that the liquid so separated would not be sufficiently free from noxious matters to allow of its being discharged at the present outfalls as a permanent measure. It would require further purification, and this, according to the present state of knowledge, can only be done effectually by its application to land."

Practice of Local Government Board.

Adrian, 107. 8. Since the publication of the last-mentioned Report it has been the practice of the Local Government Board to require, save in exceptional cases, that " any scheme of sewage disposal, for which money is to be borrowed with their sanction, should provide for the application of the sewage or effluent to an adequate area of suitable land before its discharge into a stream." There can be no doubt, in our opinion, that the Local Government Board were bound, under the circumstances, to insist upon such a rule.

Reasons for Reconsidering Position.

Tatton, 261, 284, 402–4, 6632. Naylor, 931. Barwise, 4028. Maclean Wilson, 6138–9. 9. It is now contended that in many cases, especially in the great centres of manufacturing industry, the land available is either of unsuitable quality, is available in quite inadequate area for effective filtration through the soil, or is obtainable only at a prohibitive cost, and it is suggested that sewage purification may, in such cases, be carried out on comparatively small areas artificially prepared. During recent years a variety of artificial processes, differing from those which were considered by the earlier Commissions, have been elaborated for treating sewage, and it is urged that satisfactory effluents can be obtained by such artificial processes.

Scope of Work of this Commission.

10. Having regard to the definite findings of previous Commissions, to the consequent practice of the Local Government Board in insisting on the provision of land for the purification of sewage, and to the fact that the artificial processes are still only in the experimental stage and, as might be expected therefore, the evidence in regard to them is inconclusive on many points, it has appeared to us essential to subject the artificial processes to sustained examination, and also carefully to test the contention that in certain cases it is not practicable to purify sewage by land treatment.

11. At the time of the investigations of the earlier Commissions, the science of bacteriology was in its infancy, and these Commissions confined themselves almost entirely to a chemical examination of sewage effluents. Since the dates of those Commissions a large amount of exact knowledge has been gained concerning the part played by bacteria in various processes of nature and operations of man, and it became our duty to study the various questions connected with sewage disposal, not

only from a chemical but from a bacteriological point of view as well. This has largely increased our labours, but we trust will also largely increase their usefulness. We have had to initiate and carry out various bacteriological investigations, and, in particular, finding that the work done by earlier Commissions in regard to land treatment was not complete enough for our purposes, we have thought it necessary to include in our work a systematic investigation, bacteriological as well as chemical, of the treatment of sewage on land of various kinds. This investigation is on the point of completion.

12. For the purpose of our own work we appointed the following officers :— Officers appointed.

Professor Boyce, Bacteriologist.
Dr. Houston, Bacteriologist.
Dr. McGowan, Chemist.
Mr. Colin Frye, Chemist.
Mr. G. B. Kershaw, Engineer.

Question I. :—Are some sorts of Land Unsuitable for the Purification of Sewage.

13. As regards the allegations that certain sorts of land are so unsuitable as to render them practically useless for the purification of sewage, we have received evidence from a number of witnesses who have had much experience of sewage treatment. Almost without exception their testimony is to the effect that peat and stiff clay lands are unsuitable for the purification of sewage. Conclusions as to certain sorts of land.

14. Our own officers have made a large number of analyses of effluents from well-managed farms with different classes of soil, and their results support this general opinion.

CONCLUSION 1.

15. We doubt if any land is entirely useless, but in the case of stiff clay and peat lands the power to purify sewage seems to depend on the depth of the top soil.

There are, of course, numerous gradations in the depths of top soil which are met with in nature, and it is not easy to draw the line between lands which contain a sufficient depth to justify their use, and lands which do not.

We are, however, forced to conclude that peat and stiff clay lands are generally unsuitable for the purification of sewage, that their use for this purpose is always attended with difficulty, and that where the depth of top soil is very small, say six inches or less, the area of such lands which would be required for efficient purification would in certain cases be so great as to render land treatment impracticable.

Further information with regard to this point will be available when our investigation of Land Treatment is completed.

Question II. :—Is it practicable uniformly to Produce by Artificial Processes alone an Effluent which shall not Putrefy and so Create a Nuisance in the Stream into which it is Discharged.

16. The following general classification will serve to show the nature of the artificial processes to which we refer :— Purification obtainable by artificial processes.

Closed septic tank and contact beds.
Open septic tank and contact beds.
*Chemical treatment, subsidence tanks, and contact beds.
Subsidence tanks and contact beds.
Contact beds alone.
Closed septic tank followed by continuous filtration.
Open septic tank followed by continuous filtration.
Chemical treatment, subsidence tanks, and continuous filtration.
Subsidence tanks followed by continuous filtration.
Continuous filtration alone.

---

* The expression "subsidence tanks" is intended to denote tanks which are used in such way that little or no "septic" action is produced.

17. Many valuable experiments on artificial treatment have been made by a number of local authorities, and in particular the Corporations of Leeds and Manchester have subjected certain processes to sustained observation. In this way much reliable information has been obtained.

18. We are not, however, in a position to express an opinion upon the relative merits of the several artificial processes, nor can we at present make a complete comparison between land treatment and artificial treatment of sewage, or state how far purification of sewage can be uniformly effected by one or another artificial process, and at what cost as compared with land treatment.

The character of the sewage of different towns varies to a considerable extent, especially in respect to the amount and nature of the trade refuse mixed with the domestic sewage, but also in respect to domestic sewage itself; and a method applicable to one sewage might not be applicable to another. The problems involved in the matter are so many and so varied that only investigation, and, we may add, experience of a prolonged and varied character, will suffice to solve them.

CONCLUSION 2.

19. After carefully considering, however, the whole of the evidence, together with the results of our own work, we are satisfied that it is practicable to produce by artificial processes alone either from sewage, or from certain mixtures of sewage and trade refuse such, for example, as are met with at Leeds and Manchester, effluents which will not putrefy, which would be classed as good according to ordinary chemical standards, and which might be discharged into a stream without fear of creating a nuisance.

We think, therefore, that there are cases in which the Local Government Board would be justified in modifying, under proper safeguards, the present rule as regards the application of sewage to land.

No general rule as to what these safeguards should be can be laid down at present, and indeed it will, probably, always be necessary that each case should be considered on its own merits.

Bacteriological Qualities of Effluents. Sewage Effluents in Relation to Disease.

20. As we have already said sewage effluents must, in accordance with present knowledge, be judged not only from a chemical but also from a bacteriological point of view. In order to safeguard public health, it is, in certain cases at any rate, not enough to know the chemical features of an effluent and to ascertain that it will not putrefy of itself, we must know the bacteriological features as well.

Thomson, 1392. Adeney, 2445–6. Marshall Ward, 2653–5; 2727–2748. Woodhead, 2988. Frankland 3043–8. Roscoe, 3653–5; 3662. Barwise, 4041. Rideal, 4406. Thresh, 8956–7.

21. Several witnesses have referred to the danger of allowing pathogenic organisms to enter streams which are used for drinking purposes, and our own officers are carrying out careful prolonged investigations on this matter.

We are impressed with the great importance of the bacteriological questions which have arisen in the course of our Inquiry, but we do not, at present, feel justified in putting forward any conclusions concerning them.

We may, however, even at this stage point out, that as a result of a large number of examinations of effluents from sewage farms and from artificial processes we find that while in the case of effluents from land of a kind suitable for the purification of sewage there are fewer micro-organisms than in the effluents from most artificial processes, yet both classes of effluents usually contain large numbers of organisms, many of which appear to be of intestinal derivation, and some of which are of a kind liable, under certain circumstances at least, to give rise to disease.

We are of opinion, therefore, that such effluents must be regarded as potentially dangerous, and we are considering whether means are available and practicable for eliminating or destroying such organisms, or, at least, those giving rise to infectious diseases.

Question III. :—What means should be adopted for securing the better Protection of our Rivers.

22. From the evidence which we have received, from our own observation, and from information collected for us by the Local Government Board for Scotland, we are satisfied that the Rivers Pollution Prevention Act, 1876, has not resulted in the general purification of our rivers. Protection of rivers. Curphey 1822. Frankland, 3010.

23. This is due largely to the reluctance of the authorities to put the Act in force, but partly also to the difficulty which a sanitary authority experiences in proving that the pollution within its district comes from the district against which, or the person against whom, action is taken. An authority wishing uniformly to enforce the Act in its own district has no security that the authorities above and below it on the stream will do the same, and it is therefore naturally disinclined to take action. Tatton, 254. Curphey 1808; 1825–6. Roscoe, 3768.

24. The Local Government Act, 1888, Section 14 (1) and the Local Government (Scotland) Act, 1889, Section 55 (1), give to County Councils of England and Wales and Scotland "power in addition to any other authority to enforce the provisions of the Rivers Pollution Prevention Act, 1876, in relation to so much of any stream as is situate within or passes through or by any part of their county."

25. This concurrent power of the County Council does away with the difficulty of proving pollution within a district from a source within the area of the county, though outside the district, and it should insure equal and fair treatment for all authorities and persons within the county. Several county councils are putting the Act into operation and are making good progress.

26. Section 14 (3) of the Act of 1888 provides that "The Local Government Board by Provisional Order made on the application of the council of any of the counties concerned may constitute a Joint Committee or other body representing all the administrative counties through or by which a river, or any specified portion of a river, or any tributary thereof passes, and may confer on such committee or body all the powers of a sanitary authority under the Rivers Pollution Prevention Act, 1876, or such of them as may be specified in the Order," and similar powers are conferred on the Secretary for Scotland by Section 55 (3) of the Local Government (Scotland) Act, 1889.

27. Under the Local Government Act, 1888, the Mersey and Irwell Joint Committee, the Ribble Joint Committee, and the West Riding Rivers Board have been constituted. The evidence shows that these bodies have done much useful work in enforcing the treatment of sewage and trade refuse, and that it is of considerable importance to have for each watershed a single authority. Tatton, 256. Scudder, 497; 6149. Naylor, 845. Maclean Wilson, 1175–6. Roscoe, 3554. Hibbert, 7885–7.

The advantages a county has in enforcing the Rivers Pollution Prevention Act, 1876, are also possessed by a Joint Committee of more than one county, and are increased in proportion to the wider area.

28. But those councils or committees of more than one county who are enforcing the Act feel the injustice of compelling their authorities and manufacturers to purify their effluents, whilst in other parts of the country and over wide areas little or nothing is being done. Tatton, 273.

29. Previous Commissions have referred to the necessity of setting up watershed boards, and otherwise strengthening the machinery for the protection of our rivers, as the following extracts will show :—

Extracts from Second Report of the Commission appointed in 1857 to inquire into the best mode of distributing the sewage of towns.

"We have now to urge, as the first and all-important step towards securing this object and the "permanent improvement and protection of the rivers of the country, that a general local jurisdiction and "conservancy be created throughout the kingdom, with adequate powers and proper guarantees for their "due administration." Page 9.

* * * * * *

"The abuses and nuisances which have now grown up with the growth of towns and manufactures "urgently demand some available law for the conservancy of rivers, from their sources to their outfalls."

* * * * * *

Page 40. "Having now fully stated our conclusions as to the means of disposing of the sewage of towns, and "shown that the remedies for the evils which are experienced, although various, are both practicable and "economical, we beg to repeat our conviction that the only security for a general and continued employment "of such means will be the establishment of responsible conservancies throughout the country, armed with "adequate powers."

EXTRACTS from First Report of the Commissioners appointed in 1865 to inquire into the best means of preventing the Pollution of Rivers.

Page 32. "We also humbly submit the following Recommendations to Your Majesty :—

"That the whole river be placed under the superintendence of one governing body."

"That it be made incumbent upon the Conservators to see to the enforcement of the above prohibitions "against pollution of the river. . . ."

EXTRACTS from Third Report of the Commissioners appointed in 1865 to inquire into the best means of preventing the Pollution of Rivers.

Page 53. "Where manufactures have been established and a large resident population has grown up as before "stated, the greatest amount of pollution takes place, the area of country over which such form of nuisance "is spread having no defined boundary other than the dividing ridges of such watershed and the shores of "the sea. In order to prevent the Pollution and legally control the Management of rivers, their basins or "watersheds must be placed under supervision, irrespective of any arbitrary divisions of County, Parish, "Township, Parliamentary, Municipal, or Local Government Act boundaries; or, indeed, of any artificially "established division. Running waters flow on from their source to the sea, and if the upland waters are "polluted by town sewage and by refuse discharged from manufactures, as in the West Riding of Yorkshire, "the entire length of a river is necessarily polluted, and will require to be Conserved or protected."

Page 54. "One conclusion, therefore, forces itself upon anyone who honestly deliberates upon the existing state "of things in regard to the rivers we have visited with a view to its permanent improvement. A stronger "power than has hitherto been available must be brought to bear if the present abuse and pollution of "streams is to be arrested, and Government supervision and inspection must enforce and strengthen the "action of local authorities."

EXTRACT from First Report of the Commissioners appointed in 1868 to inquire into the best means of Preventing the Pollution of Rivers.

Separate Conclusions and Recommendations by Major-General Sir William Denison, K.C.B., *Chairman.*

Page 132. "The evidence we have had of the total disregard of mere legal enactments which tend to fetter the "actions of masses of people, of the constant evasions of obligations imposed by law, of the inefficiency of the "law, even when means have been found to bring it into action, to enforce the adoption of any special "remedy for the evils complained of, has satisfied me that it will be necessary to call into action an authority "superior to all those local municipalities, embracing in its scope the whole area of the watershed subdivided "among these bodies, and to confer upon such authority powers differing both in kind and degree from that "exercised by ordinary municipalities or conservancies."

EXTRACT from Third Report of the Commissioners appointed in 1868 to inquire into the best means of Preventing the Pollution of Rivers.

"RECOMMENDATIONS."

Page 56. "3. That all rivers and streams in England be placed under the superintendence of a central authority "or board, to be composed of not more than three persons, who shall be duly qualified to deal with all questions "connected with the pollution of water and with water supply.

"4. That it be the duty of this board to see that all enactments relating to the use or abuse of running "water be duly enforced; and that for this purpose power be given to it to inspect manufactories; reservoirs, "sewerage, and other similar works; and to cause to be constructed, at the expense of the owners of the "same, whether corporate or private, any necessary purifying apparatus, in case the said owners neglect or "refuse to provide such apparatus for themselves."

CONCLUSION 3.

30. We consider it of the utmost importance that the simplest possible means should be provided for adequately protecting all our rivers, and we are further of opinion that it will be desirable, probably for some time to come, that scientific experiments should be carried on in order to ascertain all the real dangers of pollution, against which they should be protected.

In the present state of knowledge, and especially of bacteriology, it is difficult to estimate these dangers with any accuracy, and it seems quite possible that they should be either exaggerated or undervalued according to the predisposition of those who have to deal with them. An authority, guided by medical considerations, might not unnaturally be inclined to insist on a degree of purity which may ultimately prove in certain cases to be uncalled for, while another authority, with its mind fixed upon economy, might shrink from taking essential precautions.

31. It is, perhaps, scarcely for us to say what arrangements should be made, but we are of opinion that the general protection of our rivers is a matter of such grave concern as to demand the creation of a separate commission, or a new department of the Local Government Board, which shall be a Supreme Rivers Authority, dealing with matters relating to rivers and their purification, and which, when appeal is made to them, shall have power to take action in cases where the local authorities have failed to do so.

32. We cannot conclude this Report without referring to the very serious loss which we sustained by the death of Sir Richard Thorne Thorne at a comparatively early stage of our Inquiry. He was a most active member of the Commission, and his advice and help were invaluable.

APPENDIX No. 1.

Handed in by Mr. R. A. Tatton, M.I.C.E.

REPORT to the Mersey and Irwell Joint Committee on the Treatment of Manufacturers' Waste Waters. By R. A. Tatton, M.I.C.E., Chief Inspector.

44, Mosley Street, Manchester.

To the Chairman and Members of the Joint Committee.

Gentlemen,

In accordance with your instructions, I beg to lay before you the following report on the general question of the treatment of manufacturers' waste waters :—

A Royal Commission was, as you are aware, appointed in the year 1868 to inquire into the whole question, and their report, which is very voluminous, is of the greatest importance. Another report, made by the late Dr. Angus Smith to the Local Government Board on the Rivers Pollution Prevention Act 1876, should also be brought to your notice ; it gives general rules for the treatment and precipitation of effluents from printworks, dyeworks, paper-works, etc., with particulars as to the chemicals used and the results obtained. This report is of great value. Although the exact process may require modification in different cases, it gives general lines to work upon, and, moreover, demonstrates what can be done.

The third report is that of Sir Henry Roscoe, which forms the basis on which the work of the Joint Committee has been proceeding. General rules are given for the guidance of the manufacturers, but the question of what chemicals are to be used for effecting the precipitation and subsidence which is recommended is necessarily left for each individual manufacturer to investigate for himself. Sir Henry gives as his opinion that "the best practical means for preventing pollution must be adopted."

I think the readiest way of dealing with the subject will be to give that part of Dr. Angus Smith's report which deals with effluents from printworks, dyeworks, paper-works, etc., *in extenso*, as an Appendix, referring to it from time to time as it particularly affects the different works dealt with.

Paper-works.—The question of pollution from paper-mills is dealt with in the first and fourth reports of the Commissioners. A full description is given of the process, which does not differ materially from that of the present day.

The different kinds of refuse are divided into four heads :—

1. The product from the dusting process.
2. The lime refuse from the treatment of the soda to make it caustic.
3. The alkaline waste liquor.
4. The insoluble part of the bleaching powder.

The first refuse is solid, and valuable as manure, and there is no excuse for throwing it into the river.

The second refuse, which is also valuable as manure, can be drained in pits, or it may be pressed and carted away. The same remark applies to the fourth refuse.

The third refuse the Commissioners report to be at once a source of injury, the most serious and the most difficult to meet. It consists of the alkali liquor in which the straw, esparto grass, rags, or whatever material is used in the preparation of the paper, has been boiled, and also of the water in which the material is subsequently washed. The first part of this liquor—namely, that from the boilers—is very foul ; but in cases where a large quantity of soda ash is used (as with esparto grass), evaporators may with advantage be put down, as the quantity of soda ash saved is said to pay for their erection. The remainder of the alkali liquor which comes from the washing machines (also that from the boilers if evaporators are not in use) must be treated differently, and the Commissioners report in favour of land filtration.

Since the date of the Commissioners' report, however, great progress has been made in the reduction of pollution, especially at the paper-works on the North Esk, where, in consequence of litigation with the landowners lower down the river, means for rendering the waste waters innocuous have been brought to greater perfection than perhaps anywhere else in the country. The improvements in this respect have been carried out in the manufacture of the paper itself by retaining more of the fibre, and therefore allowing less to go down the river. It is satisfactory to find that the restrictions have been the cause of a distinct saving in material to the manufacturer, all the fibre which is allowed to escape being loss to him. The most important improvement is effected by washing the esparto grass in a series of tanks after it has left the boilers, and before it goes to the ordinary washing machines. The water used in these tanks flows from one to another, and the arrangement is such that supposing the series to consist of 10 tanks each boiling of grass receives ten washings, the pure water being turned in the first instance on to the boiling, which has already been washed nine times, and finishing with the boiling which has been last brought from the boiler ; the water is then used in the boiler itself, and is finally taken to the evaporator. This system not only largely reduces the polluton by removing most of the alkali liquor before the grass goes to the ordinary washing machines, but also saves a considerable percentage of fibre. It should certainly be adopted at all mills where esparto grass and straw are used. Appendix I.

With regard to the settling tanks used on the Esk, they also show a great improvement both in economy and efficiency over the tanks in this district. All the waters not treated in the evaporators flow to the tanks, which in the most efficient systems are arranged as a series of shallow channels, 40 feet long and 2 feet in width ; the water flows over sills at each end of the channels, which must be of sufficient area to keep the water as quiescent as possible. The sludge from these tanks is dried, and if consisting of fibrous matter only, as from rag washings or from the machines, it may be sold for making inferior kinds of paper, thus making the tanks remunerative. The effluent water is finally passed through cinder filters 18 inches in depth, and care must be taken that it is either neutral or slightly acid before getting into the river.

Dr. Angus Smith's report (*see* Appendix) gives the results obtained by treating the effluent with chemicals. The precipitation takes place quicker, and consequently the tanks need not be so large ; also the treatment is more likely to be efficient without filtration, which is apt to be a troublesome process.

To summarise, I would suggest that all paper-makers who use esparto or straw in any quantity should erect evaporators and washing tanks such as I have described, and that the whole of the remainder of the waste waters should be treated in settling tanks. It might be misleading to give a minute description of the settling tanks, as different works will necessarily vary in their requirements ; but any system adopted should be planned with a view to the sludge being remunerative.

Printworks and Dyeworks.—The pollution from this class of works is caused by aniline dyes, logwood, and other wood extracts, soap, starch, fustic, soda, bleaching powder, &c. All waste waters which contain these must be treated, with the exception of the wash waters, in which the polluting matter is so small in comparison to the quantity of water used that unless unusually foul they may safely be allowed to go into the river.

In certain cases no doubt there will be a difficulty in separating the wash waters from the dye and more pol-

luted waters, and some manufacturers may find it more economical to treat the whole than to lay down a second system of drains.

For the treatment of these waste waters the Royal Commission recommend filtration through land; but as land in sufficient quantity is in most cases difficult to obtain, I think we must look to chemical precipitation, with or without subsequent filtration through artificial filters, as the process to be adopted.

One of the most efficient purification systems in the watershed consists of three brick tanks and a filter. The tanks are so arranged that the waste water can be turned through all three tanks in succession, in which case there is a constant though slow flow, or it can be turned into a single tank, allowing the other two to remain quiescent for the solid matter to precipitate. After issuing from the tanks, the effluent is passed through the filter. The filtering material used is cinders, which have been found more efficient than sand; but I think that if the sand used was of a good, sharp quality it would give better results than cinders, and be more easy to clean.

The precipitant used is put into the channel which conducts the waste water from the works to the tank, so that the whole is thoroughly mixed together before its arrival at the tank. This mixing is of the greatest importance, and on it depends the efficient action of the precipitant. It may be aided by bafflers or boards placed in the channel, to cause disturbance of the stream.

A convenient way of applying the precipitant is to have it in solution in a cask, with a tap arranged to discharge into the channel. The tap can be regulated to give the required quantity.

The effluent from the tanks is drawn off by floating valves which admit the surface water only, and which must not be allowed to sink below the depth of the clear water. The sludge below this depth must be either pumped out or run through valves in the bottom of the tank into a sludge well. Neither from the sludge well nor from these valves in the bottom must there be any communication with the river.

I have purposely given no details as to size of tanks, as such information may be misleading, but as a general rule a good system should consist in the first place of a large tank or pit containing a day's supply; into this tank the whole of the waste waters from the works should be run, "when," as pointed out by Dr. Angus Smith, "large precipitates occur, and frequently complete neutralisation arising from this—namely, that the processes have required equivalent amounts of acid and alkali, although they escape separately."

From this tank the effluent must pass by means of a channel to the precipitation tanks, and the precipitant used must be put into this channel.

The precipitation tanks should be at least two in number, and arranged to be used alternately. They should each contain half a day's supply, and be fitted either with floating valves or some other means of drawing off the clear water. The sludge may be pumped from the tanks direct, or, what is better, drawn off into a sludge-well, which will enable the tank to be got to work again quicker. What precipitant is best to use each manufacturer must decide for himself; but Dr. Angus Smith's report (*see* Appendix) gives a number of experiments, and shows what results can be obtained —in one case 99·8 per cent. of colour being removed.

Several patent processes have been brought out which deal with these waste waters in considerably less space than is required for the ordinary method; manufacturers who have not room for large tanks should consider the advisability of adopting one or other of them.

Bleachworks.—The waste waters from bleachworks vary considerably according to the class of goods dealt with.

The waste bleacher's refuse is the worst, as a large amount of oil and dirt comes away from the goods, in addition to the lime, soda, etc., used in the process. The water from the keirs in which the pieces of yarn are boiled should in all cases be treated, also all solid lime refuse must be kept out of the river; the wash waters may, as a rule, be allowed to go direct into the river except in certain cases (including waste bleaching), when part of them will require treatment. These should be concentrated as much as possible, in order to reduce the quantity.

Precipitation in tanks is probably the best treatment, as the subsidence of the solid matter is assisted by the large amount of lime in the water. The most successful system I know of in operation consists of a succession of large pools, through which the water slowly flows; it is finally passed through a cinder filter before being admitted into the river. No additional precipitant is used, but I think it probable that if one were adopted a great improvement would be the result, and the size of the tanks could be considerly reduced.

Woollen Works and Fullers.—The waste waters from these works are very offensive, and in some parts of the watershed are responsible for most of the pollution. They contain animal oils from the wool, soap, soda, and fuller's earth. These may be readily dealt with by means of precipitation and filtration, as has been proved at several works where a purification plant has been put down. The most efficient system in the watershed consists of two settling tanks, three precipitation tanks, and one sand filter. The settling tanks, which are made from two old boilers, retain most of the heavy matter and fuller's earth, and considerably relieve the precipitation tanks through which the waste water flows next; these tanks are used alternately to allow of those not in use being cleaned out. The sand filter completes the treatment. Alumino ferric is the precipitant used, and is introduced into the channel leading to the settling tanks. Another firm has lately been experimenting with sulphate of iron and lime with good results.

Sap-pits for the recovery of the soap, which have been almost universally adopted, can be used in conjunction with a system similar to the above.

Dr. Angus Smith gives a large number of experiments with various precipitants, particulars of which will be found in the Appendix.

The Royal Commissioners in their report recommend application to land, either by irrigation or intermittent filtration, as the best means of dealing with these liquids. This plan might well be adopted where land can be obtained in sufficient quantity and of suitable character, or land might be used instead of the sand filter after the water has passed through the precipitation tanks.

Very efficient plant has been erected at the woollen mills at Galashiels, and the effluent obtained is good enough, in the estimation of Mr. Fletcher (Inspector under the Rivers Pollution Act), to entitle the manufacturers to a certificate under the Act. The waste water is very foul—the impurities consisting of soap, animal grease, and dyes—the result of every stage of manufacture from the fleece to the finished cloth. The different waters are purified by precipitation in tanks—lime being used with the dye and acid with the soap liquors; the two being finally mixed together and further neutralised if necessary before being admitted into the river. The precipitation of the solids is aided by the introduction of air forced through perforated pipes into the tanks. One man is continuously employed attending to the tanks and pipes, etc., connected with them. This system is probably the most efficient in the country, and has been universally adopted on the River Gala, the water of which must previously have been seriously polluted.

Silkworks.—The chief pollution from these works is caused by the gum, which is removed from the raw silk by washing in a solution of soap. The waste may be treated by processes well known to the silk manufacturers. The dye-water will require treating in the same manner as from print and dye-works.

Chemical Works.—The waste waters from this class of works are so various that it is impossible to lay down any general rules for their treatment, as stated in Sir Henry Roscoe's report. Each case will require to be taken separately, the composition of the effluent water ascertained, and if inadmissible either into the river or sewers, some means of chemical treatment adopted. It might perhaps be possible to have a schedule drawn up, showing how the usual products which are run to waste may be dealt with, and whether they are admissible into the river or sewers.

Breweries.—The washings of barrels, fermenting vats, and cooling tanks make up the waste waters from these works. The refuse is of a very obnoxious character, and seriously pollutes any stream into which it is discharged. It should be precipitated in tanks, and subsequent filtration would probably be attended with good results.

Tanneries and Fellmongers.—The waste waters from these works are most offensive, and must be rigorously excluded from the streams. The readiest means of dealing with them, after passing them through tanks to intercept the bulk of the solid matter, is to admit them into the sewers. The quantity of water used is not large. If there are no sewers near the works, some treatment must be adopted; probably a treatment similar to one of those adopted at sewage works would prove the most efficient. One manufacturer has put down a precipitation tank and filter which does its work fairly efficiently.

Slack Washing is a process employed at some collieries for separating small coal, which would otherwise be of little value, from the refuse with which it is mixed when brought up from the pit. The effluent water contains a large amount of solid matter in suspension; it may readily be treated by passing it through settling tanks, which should be put down at all collieries where this process is used.

I have endeavoured to put before your Committee a description of the various kinds of pollution, and the best available methods of dealing with them. It has not been possible within the compass of this report to go into great detail, nor is it requisite to do so. General rules only can be given, which must be adopted to the requirements of each individual works. Any further information which we have or can obtain is at the service of anyone desiring it.

I am, etc.,

R. A. Tatton.

February 16th, 1893.

APPENDIX.

Extract from report of Dr. Angus Smith to the Local Government Board.

Effluents from Printworks, Dyeworks, etc.
Precipitation.—General Rules.

If the effluents from dyeworks or printworks are alkaline, containing organic substances coloured or otherwise, an acid generally throws down a decided amount of solid matter. If the effluent contains soap, the fatty matters are separated, and fall or rise to the surface. These fatty matters may contain a large amount of colouring matter which may or may not be of value.

If acid is expensive at the place of precipitation a similar result can be obtained by chloride of calcium or any cheap metallic or earthy salt. Chloride of calcium is the simplest, and has a great influence. Its effect is not limited to the soap, but is observed in the effluents from paper-works, and other cases where the liquids are alkaline.

Salts of calcium are, therefore, very valuable; and as they are found at bleachworks, printworks, and paper-works, and wherever bleaching is done, they have a great influence on the discharges. This influence is not always seen at once; it requires some time, and it would appear as if settling tanks were absolutely necessary. It would be very good if we could hasten this precipitation. To some extent this is done by adding metallic or aluminous salts, but it is done also by stirring or shaking, as we often find in a laboratory, and previous to allowing the solution to rest. Thinking of this, one would have supposed that very violent action would have assisted still more the fall; but this was not the case. We found that by agitating the effluents after mixture with the precipitant, these could be reduced to a state of division so fine as to delay their fall.

The advantages of chloride of calcium are that it is frequently a waste product, and a great deal could be obtained if it were wanted.

Lime will certainly throw down the fatty matter of soap, and it will also take a great deal of solid matter out of the effluents of paper and other works but it will not neutralise in such cases; on the contrary, it causticises these liquids. Chloride of calcium also can be thrown in considerable quantities into a river without injury, whereas this is not the case with lime.

The first thing to be done with the effluents from works generally is to allow them all to mix together, when large precipitates occur, and frequently complete neutralisation, arising from this, namely, that the processes have required equivalent amounts of acid and alkaline, although they escape separately. Cases exist, however, in which such a mixture would be of no advantage; and in other cases, as in alkali works, the mixture of the acid and sulphide liquors produces intolerable results.

The works, however, specially under consideration give out liquids which by this treatment cause considerable and sometimes large precipitates. The addition of chloride of calcium causes a second precipitate frequently, and it may be that this will be in some cases a sufficient treatment.

When better results are required, it is apparently essential to use salts of iron or aluminum; and few waters from these works under consideration will not become clear after this treatment; most, if not all, can be made also nearly colourless.

It would be quite wearisome to detail all the experiments made to come to these conclusions, but various results will be here given, and they may be compared also with those from sewage treatment.

Effluents from Paper Works.—May, 1878.

Discharge Water from Settling Ponds, Carron Grove Works.—19th April, 1878.

(1.) After filtration,—
10 lbs. Alum, 2·5 lbs. Lime } per 1,000 galls.
Volatile = 4·9 gr. per gall.
Mineral = 65·94 ,,
Total = 70·84 ,,
The filtrate was slightly acid; colour = 0·1 c. c. NH_4Cl with Nessler. No permanent froth on shaking.

(2.) After filtration,—
8 lbs. Alum, 2·5 lbs. Lime } per 1,000 galls.
Volatile = 5·67 gr. per gall.
Mineral = 57·33 ,,
Total = 63·00 ,,
The filtrate was faintly alkaline; colour = 0·4 c. c. NH_4Cl with Nessler. No permanent froth on shaking.

(3.) After filtration,—
4 lbs. Alum, 2·5 lbs. Lime } per 1,000 galls.
The filtrate decidedly coloured. Permanent froth on shaking.

Sample received 29th April, 1878.

(4.) After filtration,—
10 lbs. Alum, 2·5 lbs. Lime } per 1,000 galls.
Volatile = 0·28 gr. per gall.
Mineral = 76·16 ,,
Total = 76·44 ,,
Similar to No. 1.

(5.) After filtration,—
8 lbs. Alum, 2·5 lbs. Lime } per 1,000 galls.
Volatile = 11·48 gr. per gall.
Mineral = 77·55 ,,
Total = 89·04 ,,
Similar to No. 2 as to froth. Filtrate slightly coloured.

(6.) After filtration,—
6 lbs. Alum, 2·5 lbs. Lime } per 1,000 galls.
Filtrate decidedly coloured. Froth lingered slightly.

Sample received 19th April, 1878.

(7.) After filtration,—
2·5 lbs. $Fe_2(SO_4)_3$, per sulphate of iron. Lime quant. suff. } The lime was added immediately after the iron sol. Filtrate slightly coloured.

(8.) After filtration,—
1·25 lbs. $Fe_2(SO_4)_3$, Lime quant. suff. } The lime was added five minutes after the iron sol. Filtrate was colourless.

(9.) After filtration,—
0·7 lb. $Fe_2(SO_4)_3$, excess powdered chalk } The ppt. settled readily. Filtrate clear; did not froth.

Clarification of Logwood Waste Liquors.—March, 1879.

Exit Liquor from Works.

(1.)	100 lbs. Alum Cake, 7·5 lbs. Lime	per 1,000 galls.	Colour almost gone.
(2.)	20 lbs. Alum Cake, 1·5 lb. Lime	per 1,000 galls.	97 % colour removed.
(3.)	10 lbs. Alum Cake, 0·76 lb. Lime	per 1,000 galls.	95 % colour removed.
(4.)	6 lbs. Alum Cake, 0·76 lb. Lime	per 1,000 galls.	90 % colour removed.
(5.)	4·74 lbs. Ferric Chloride, 6·00 lbs. Lime	per 1,000 galls.	99·8 % colour removed.
(6.)	2·16 lbs. Ferric Chloride, 4·56 lbs. Lime	per 1,000 galls.	98 % colour removed.
(7.)	0·66 lb. Ferric Chloride, 2·28 lbs. Lime	per 1,000 galls.	70 % colour removed.

Note.—There was a little free HCl along with the Fe_2Cl_6, ferric chloride or perchloride of iron.

(8.) 18·5 lbs. hydrated alumnia per 1,000 galls. 60 % colour removed.

(9.) 4·12 lbs. Fe_2Cl_6, 12·5 lbs. HCl, 5·0 lbs. Lime } per 1,000 galls. Colour destroyed. The ppt. settles rapidly and perfectly.

(10.) 2·1 lbs. Fe_2Cl_6, 6·25 lbs. HCl, 2·5 lbs. Lime } per 1,000 galls. Colour destroyed. The ppt settles rapidly and perfectly.

(11.) 1·25 lbs. Fe_2Cl_6, 2 lbs. Lime, 3·75 HCl } per 1,000 galls. Filtrate faintly coloured. Ppt. settled fairly, but left a turbidity in the liquid, which, however, was readily removed by filtration.

(12.) 0·85 lbs. Fe_2Cl_6, 2·5 lbs. HCl, 1·5 lbs. Lime } The ppt. behaved as in No. 11, but the filtrate was distinctly coloured.

(13.) 200 lbs. $CaCl_2$, chloride of calcium, per 1,000 galls. removed 60 % of the colour.

Appendix I

Clarification of Liquors from Woollen Mill.

Contents of last Tank before entering "Lade," Copperas, or protosulphate of iron, or ferrous sulphate.

(a.)	8 lbs. Ferrous Sulphate 0·5 lbs. Lime	per 1,000 galls.	66 % colour removed.
(b.)	8 lbs. Ferrous Sulphate	per 1,000 galls.	39·3 % colour removed.
(c.)	12 lbs. Ferrous Sulphate 0·5 lbs. Lime	per 1,000 galls.	84·5 % colour removed.
(d.)	12 lbs. Ferrous Sulphate	per 1,000 galls.	78·7 % colour removed.
(e.)	2·6 lbs. Fe_2Cl_6 (?) Lime	per 1,000 galls.	89·4 % colour removed.
(f.)	8 lbs. Alum 0·5 lb. Lime	per 1,000 galls.	71 % colour removed.
(g.)	8 lbs. Alum	per 1,000 galls.	72·5 % colour removed.
(h.)	6·5 lbs. Fe_2Cl_6 5·6 lbs. Lime	per 1,000 gals.	95·6 % colour removed.

(i.) No. (h) with 8 lbs. Copperas per 1,000 galls. 98·9 % colour removed. The ferrous salt was added to destroy the chromate which was left by the ferric salt.

(j.)	3·7 lbs. Fe_2Cl_6 8·0 lbs. Copperas 2·75 lbs. Lime	per 1,000 galls.	96·5 % colour removed.
(k.)	3·7 lbs. Fe_2Cl_6 20 lbs. Copperas 2·75 lbs. Lime	per 1,000 galls.	97 % colour removed.
(l.)	7·4 lbs. Fe_2Cl_6 4·0 lbs. Copperas 5·5 lbs. Lime	per 1,000 galls.	96·5 % colour removed.
(m.)	3·7 lbs. Fe_2Cl_6 2·75 lbs. Lime	per 1,000 galls.	92 % colour removed.

(n) No. (m) with 8 lbs. $FeSO_4 . 7 H_2O$ per 1,000 gals. No further change. Comp. (h) and (i).

(o) No. (n) with 1·4 lbs. Lime per 1,000 galls. 98·2 % original colour removed.

The liquid flowing from the ppt. obtained in expt. (j.) gave—

Volatile matter	8·4 grs. per gall.
Mineral „	24·5 „
Total	32·9 „

Before clarification the liquid contained—

Volatile matter	81·9 grs. per gall.
Mineral „	119·0 „
Total „	200·9 „

(p)	5 lbs. $CaCl_2$ 1·5 lbs. Fe_2Cl_6 11·0 lbs. SO_3	per 1,000 galls. (neutral iron sol.)	Filters slowly. Filtrate coloured blue.
(q.)	5 lbs. $CaCl_2$ 1·5 lbs. Fe_2Cl_6	per 1,000 galls. (neutral iron sol.)	Similar to (p.)
(r.)	5 lbs. $CaCl_2$ 1·5 lbs. Fe_2Cl_6 with 3·0 lbs. HCl (Acid solution of iron.)	per 1,000 galls.	Filters clear. Filtrate slightly yellow.
(s.)	5 lbs. $CaCl_2$ 1·5 lbs. Fe_2Cl_6 2·0 lbs. HCl	per 1,000 galls. (neutral iron sol.)	Filtrate blue and turbid.
(t.)	5 lbs. $CaCl_2$ 1·5 lbs. Fe_2Cl_6 3·0 lbs. HCl	per 1,000 galls. (neutral iron sol.)	Filtrate coloured; not very clear.
(u.)	5 lbs. $CaCl_2$ 3 lbs. HCl.	per 1,000 galls.	

To the filtrate from the foregoing—

2 lbs. Fe_2Cl_6 (neutral) per 1,000 galls.
? Lime (till faintly alkaline). — The filtrate from the iron was good.

(v.)	5 lbs. $CaCl_2$ 4 lbs. SO_3, sulphuric acid calculated as anhydride.	per 1,000 galls.	Filtrate slightly alkaline.
(w.)	5 lbs. $CaCl_2$ 20 lbs. SO_3	per 1,000 galls.	Filtrate slightly turbid.

Mixture of Polluted Liquids from Woollen Mills.

20 lbs. sulph. acid 4·12 lbs. Fe_2Cl_6 12 lbs. CaO	per 1,000 galls.	Filtrate colourless.
20 lbs. sulph. acid 0·82 lb. Fe_2Cl_6 5·0 lbs. CaO	per 1,000 galls.	Filtrate colourless.
lbs. O. V. 0·41 lb. Fe_2Cl_6 4·0 lbs. CaO	per 1,000 galls.	Filtrate slightly coloured.
5 lbs. $CaCl_2$ $8\frac{1}{4}$ lbs. Fe_2Cl_6 CaO	per 1,000 galls.	Colourless.
2·5 lbs. $CaCl_2$ 2·1 lbs. Fe_2Cl_6 6·6 lbs. HCl ? CaO	per 1,000 galls.	Colourless.

APPENDIX No. 2.

Handed in by Mr. W. NAYLOR, F.C.S., Assoc. M. Inst. C.E.

REPORT on the NATURE and TREATMENT of MANUFACTURERS' WASTE EFFLUENTS.

By W. NAYLOR, F.C.S., Assoc. M. Inst. C.E.

RIBBLE JOINT COMMITTEE.
Walton's Parade, Preston,
March, 1893.

To the Members of the Sub-Committee appointed to consider the Pollution of Rivers by Manufacturers' Waste.

Gentlemen,

As instructed at the meeting of the Ribble Joint Committee in December last, I beg to present herein the main facts to be considered in dealing with the cases of river pollution by industrial waste, which were then referred to you by that Committee.

The branches of industry concerned are:—

1. Bleaching (Cotton).
2. Dyeing and Colour Printing (Cotton).
3. Paper Manufacture.
4. Tanning.
5. The Manufacture of Alkali and various Chemicals.

Before methods of dealing with the different kinds of refuse are considered, it would be perhaps desirable to give an idea as to what each kind of waste practically consists of.

FIRST.—BLEACHING COTTON.

The object of the calico bleacher is to remove as much of the foreign and objectionable matter from the woven fabric as possible. This consists of the natural resinous, fatty, waxy colouring and albuminous matter and the artificial matter introduced in the sizing of the warps, as well as adventitious dust, dirt, and grease.

The nature of weavers' size varies in different mills, some sizes being subject to patent law.* The composition of a common size, without loading, is given by O'Neil as follows:—1cwt. of potato starch, 6lbs. of tallow, 6lbs. of soap, 1lb. of sulphate of copper; the woven fabric to contain five per cent. dry. Appendix 2.

A loading is often added which may bring the percentage of size to even 30, though calico printers as a rule work with pieces containing less than this amount.

Assuming the calico to contain only five per cent., then, when 10,000 pounds weight of cloth is put into the kiers, a bleacher has to deal with 30lbs. of tallow, fatty salt of copper equal to 15lbs. of tallow, and 448lbs. of starch, or nearly 5cwt. as the lowest total.

The process of bleaching, though differing in almost every mill according to the market supplied or as to whether it be for dyeing or printing only, is in Lancashire mills substantially as follows:—

1. The pieces are washed to remove loose dirt and to soften the starch, etc. (steeping).
2. Boiled in milk of lime to decompose waxy, greasy, and resinous matters as well as soluble soaps into insoluble soaps.
3. Washed. Some weavers' starch lost.
4. Passed through a sour of weak acid. Lime soaps converted into fatty acids and salts of calcium. Any lime left in cloth is dissolved, as are also any metals in size.
5. Washed.
6. Boiled in resinate of soda or alkaline substitute. Fatty acids dissolved. Vegetable brown colours loosened.
7. Washed.
8. Passed through chlorine solution or "chemic." Colouring matter bleached.
9. Washed (sometimes omitted).
10. Soured again in weak acid.
11. Washed for final cleansing.

In order to note exactly the extent of pollution caused by each of these steps in the process of bleaching, samples were obtained through the kindness of Mr. Wood, from Brinscall Bleach and Print Works in January, 1893, which gave results as follow:—

* Patent No. 62, January, 1874:—40lbs. of sago, 10lbs. of flour, 10 gallons of water, 1lb. of paraffin or white wax, 2lbs. of tallow, 2lbs. of soap, 2oz. French chalk, 1 gill or more of mixed boiled linseed or castor oils; there may also be added gum guiacum, neatsfoot, or cocoa oil, and spermaceti.

Series A.—BLEACHING PROCESS AT WOOD'S, BRINSCALL.

Appendix 2.

In this series of analyses it will be noticed that the bulk of the solids lie in—

Series A[1].	Organic Solids.	Inorganic Solids.	Total Solids.	Relative Volume.	Product of Relative Volume and Total Solids.
				Gals.	
The First Steep.	201·0	59·3	260·3	20,000	5,206,000
Spent Lime from Keir.	718·8	143·3	862·1	1,600	1,379,360
Grey Sour -	187·3	297·7	485·0	1,600	776,000
Spent Ash -	556·4	802·1	1,358·5	1,400	1,901,900

The sum of the relative volumes of these liquors compared with the whole volume of waste is as 1 to 4.

If the relative volume of the water used in any particular step of the process be multiplied by the total solids, the product will, of course, be the relative amount of solids carried out into the river by the water used in this step of the process. (To convert parts per 100,000 to grains per gallon multiply by ·7.)

Estimated in this manner, the total solids contained in these four (Series A1) together, are to the total solids in the whole of the water turned out, as 9 to14.

Since then these liquors forementioned (A1) constitute only one-fourth of the whole, but contain nine-fourteenths of the solids, the question arises as to whether it should not be made compulsory to treat these liquors at least, and the option given as to whether the others be treated or not.

It follows, too, that the remaining liquors amount to three-fourths of the whole, but only contain five-fourteenths of the total solids.

The recommendation to pass away as harmless the waste waters was made by Sir Henry Roscoe in the preliminary report submitted to "The Mersey and Irwell Joint Committee" in March last, and previously to this by the Rivers Pollution Commissioners.

It should also be pointed out that the ratio of organic to inorganic matter in the forementioned A1, is as 16·5 to 13, and in the remaining six as 21 to 37, which indicates greater liability to decompose in the series A1.

The remaining six alluded to are—

—	Organic Solids.	In-organic Solids.	Total Solids.	Relative Volume.	Product of Relative Volume and Total Solids.
				Galls.	
Wash out of Lime Keir -	35·4	29·6	65	20,000	1,300,000
Wash out of Grey Sour -	32·7	46·1	78·8	20,000	1,576,000
Wash out of Ash Keir -	29·2	33·7	62·9	20,000	1,258,000
Spent "Chemic" - -	41·3	122·9	164·2	1,600	262,720
White Sour - - - -	54·6	127·7	182·3	1,600	291,680
Wash out of White Sour	23·3	11·1	34·4	20,000	688,000

After those liquors referred to as being the worst, come the "Spent Chemic" and "White Sour" in order of contaminating tendency; and as the relative volume of these two is but 3,700, they would be advantageously classed with the first four as requiring treatment.

But it should be borne in mind that in many instances bleach, dye, and paper works, are laid out in such a manner as to preclude the separation of the liquors in this way without entailing considerable expense. The keirs, becks, washing machines, etc., are placed sufficiently low to allow of being fed from the water supply by gravitation, and the outlets placed just sufficiently high to reach the water line of the river a little above its normal flow.

Delivery pipes from the various machines are run here and there in every direction, dodging first one obstacle and then another according to circumstances, but eventually reaching the river.

In each of such cases, a systematic mode of concentration or rejection of liquors for treatment would necessitate the movement of machines, upraising of floors, or multiplicity of pipes to an extent beyond all reason, and no course is left but to subject the whole of the effluent (mixed) to treatment.

In addition too, to the *quantity* of solids borne by a bleacher's waste, the amount of organic matter therein also demands notice. Bleachers, I fancy, get credit generally for much purer effluents than they really turn out.

The process of bleaching is essentially a process of washing, and the objectionable matter washed out is more liable to decomposition than appears at first sight.

Professor Hummel (Dyeing and Calico Printing) speaks on this subject as follows :—

"In bleach works the refuse liquids consist of alkaline and soapy solutions, together with such as contain calcium chloride, traces of bleaching powder, and free acids. Here are all the elements necessary to mutual purification, if allowed to mix together in due proportions; the calcium will precipitate the soap solutions, while the free acids will neutralise and precipitate the alkaline liquids and decompose the waste solutions of bleaching powder."

With very great care this statement may no doubt be verified on the part of the bleachers, but, unfortunately, conveniences for the detention of one liquor until a favourable opportunity for its action upon another are not always to hand, and there is certainly no case in the Ribble Watershed where such a course is followed. The idea, nevertheless, has been laid hold of and contorted into every imaginable form, until now one is often informed with childlike assurance that bleach waste has only to be admitted to the river, when it will purify itself and the river afterwards for miles.

The reservoir or lodge immediately above the Pincroft Dye Company, Adlington, which is fed principally by water containing bleach waste from works higher up the stream, in summer becomes neither more nor less than a huge, stinking cesspool, bubbling continually with gases which arise from decomposing sludge.*

The following analyses of bleach liquor indicate its putrescent nature, though it will be noticed the organic nitrogen is small in quantity.

* The lodge was let down on 9th March, 1893, owing to an accident to the dam, when I saw on the bottom 15,000 tons of sludge. Some years ago an attempt was made to empty it, but after a few days the idea was abandoned.

Series B.—Analyses of Average Bleach Waste showing Organic Matter. Appendix 2

Number of Sample.	Date.	Nature of Sample.	Parts per 100,000. Total Solids.	Free Ammonia.	Nitrogen as Nitrites and Nitrates.	Chlorine.*	Organic Carbon.	Organic Nitrogen.	N / C	Inorganic Nitrogen.	Total Nitrogen.

* Due principally to acids. † Coloured by "back pieces."

Note.—The above samples and all to follow were accepted from manufacturers as *bona fide* specimens of waste, but can only be strictly considered as such for the time defined.

Second.—Dyeing and Calico Printing.

Dyeing.

Dyeing is briefly the process of passing fabrics through solutions of colouring matter, under conditions favourable either to the temporary or permanent retention of the colouring matter by the fabric. There are many colours which, though not readily absorbed by the fabric itself, are capable of fixing themselves upon some agent with which the fabric may be saturated, which agent is termed a mordant. Different mordants are used for different colours, one colouring agent often changing its tone altogether with a different mordant.

The colours used in the Ribble Watershed are principally alizarine, logwood, and indigo, from which there is no waste thrown into the river until after the point of making coloured solutions or dyes.

Goods are passed through the solutions after mordanting, then washed; certain colours are afterwards soaped also, that they may acquire a finished, polished, or brighter appearance, and then washed again.

Calico Printing.

Calico printing is the art of dyeing designs topically upon calico having either a white or already coloured ground. The colour is first placed upon wooden blocks or engraved copper cylinders, from which it is afterwards transferred to the fabric. This causes calico printers' waste liquor to be of a more obnoxious character than that from dyers, for before the colour will adhere to the blocks or engraved cylinders it must be thickened by a paste, which paste is afterwards washed out, the colour being left behind. The principal thickening agents are:—Albumen, casein, china clay, pipe clay, dextrin, glue, gluten, glycerine, gum senegal, gum tregacanth, molasses, lead sulphate, potato starch, salep, shellac in borax, sugar, wheat flour, wheat starch, zinc chloride, and zinc nitrate. (Gardner).

The "whites" or pieces to be printed are run between the plain and engraved cylinders, together with blankets and "back pieces" or "back greys," which in due course become themselves smeared or coloured, and upon being washed and bleached give a colouration to the bleach waste.

Appendix 2.

Series D.—Analyses of Average Dye and Calico Print Waste.

SHOWING ORGANIC MATTER.

Number of Sample.	Date.	Nature of Sample.	Total Solids.	Free Ammonia.	Nitrogen as Nitrates and Nitrites.	* Chlorine.	Organic Carbon.	Organic Nitrogen.	C/N	Inorganic Nitrogen.	Total Nitrogen.
118	3 Feb. 1893 -	Sample of Waste Dye (analine) and thickening, Grafton & Co., Accrington.	204·3	·27	0	30	6·58	·329	20 to 1	·22	·549
130	10 Feb. 1893 -	Samples of Dye Waste (analine), Stanning's, Leyland.	220·0	·36	1·2	37	33·71	3·09	11 to 1	1·49	4·58

* Due principally to acids.

It will be seen from these analyses that the character of dyers' refuse is almost as objectionable as it appears. The colour itself, however, is very difficult to obliterate entirely, though this can be done with proper appliances as will be seen later. A small quantity of colour will give a very decided tint to a large volume of water,* the amount left in the dye becks to be thrown away being only that which remains unabsorbed after it has been worked until its value is less than the cost of running the machinery. The chances of its being removed in the becks at any time are small, for since these are heated by steam in contact with the liquor, which steam is continually condensing, the volume of dye liquor is continually increased, and the strength decreased accordingly, and the weaker the strength of the liquor the longer the time required for a given piece of fabric to abstract the colour. An excess of colour is always added too, otherwise processes which now require hours would require months. The thought of abstracting all dye in the dye-house must therefore be dismissed until mordants are discovered which will take up all the colour from solution, and that quickly.

The Treatment of Bleach and Dye Waste.

A.—Bleach Waste.

The efforts recently put forth by local governing authorities to prevent that pollution of streams which has been steadily increasing for years with the increase of population and development of industry, has caused to be put upon the market appliances and agents, whose name is legion, for the purification of waste liquors. Summed up they are methods of—

1.—Filtration.
2.—Precipitation.

Prior to the consideration of these methods of treatment, let it again be noted that the liquor now in question is one having abundance of solids both in solution and suspension, a considerable proportion of each being of a somewhat decomposable nature.

The purification of this liquor therefore means the reduction to a rational extent of—

1.—The suspended solids.
2.—The dissolved solids.

Now filtration, with any sense of modesty, claims nothing more than the mechanical separation of suspended solids by means of a permeable diaphragm. True, some of the very extensive sand filters for potable waters may abstract a proportion of dissolved matter, but no practicable filter for manufacturers' waste can do this, and the filtrate, though presenting often a satisfactory appearance, contains much that is to be objected to in solution, *this dissolved matter being liable to precipitate itself later on in the river bed.*

Herein lies the great objection to mechanical filters; the clear filtrate, *almost saturated with dissolved matter*, will often deposit a large amount even upon being left alone in a bottle, while the probability of such a deposition in a stream when in contact with liquors of dissimilar nature is even greater.

These remarks, it will be noted, do not refer to sewage filtration where bacteriological influences are at work. A manufacturer's filter to be of use must be quick—aided by steam, pneumatic or hydraulic pressure—and frequently washed out, thus destroying the effects of any microbes, if present, and their presence is doubtful.

Turning now to precipitation the questions present themselves:—

1.—Will precipitation remove all or any suspended matter?
2.—Will it increase or decrease the dissolved matter?
3.—How is the organic dissolved matter affected?

It will be necessary first to choose a precipitant from the host for which many virtues are claimed. In this choice I have been guided by the report of Dr. Angus Smith, F.R.S., 1882, to the Local Government Board, on the Rivers Pollution Prevention Act, 1876—a copy of which is forwarded with this report.

On page 82 *et seq.*, it will be seen that Dr. Smith relied upon the heavy precipitate formed when a solution of an iron salt is brought in contact with milk of lime. In dealing with sewage precipitants something more might be said concerning the claims of other agents, but for trade waste, though very many precipitants have appeared since 1882, iron salts appear to be the keynote of all. They may be adulterated, renamed, or patented, *but iron salts are nearly always there.*

For bleach waste I have tried, in many proportions, for this report, ferrous sulphate and milk of lime with satisfactory results. From the experiments made, I will only abstract that with bleach waste from the Whalley Abbey Print Works, which was the waste containing about the greatest quantity of total solids before treatment.

* ·05 grammes of indigo will colour 20,000,000 times the quantity of water, on a white ground, at a depth of 1 metre (39 inches).—Dr. Fleck.

Series E.—Analyses showing Result of Treatment by Lime and Iron Salts.

Number of Sample.	Date.	Nature of Sample.	Dissolved Solids. Mineral.	Dissolved Solids. Organic.	Total Dissolved Solids.	Suspended Solids. Mineral.	Suspended Solids. Organic.	Total Suspended Solids.	Total Solids.	Organic Carbon.	Organic Nitrogen.	Free NH_3.	Remarks.
129	9 Feb. 1893 -	Whalley Abbey bleach waste collected at three hourly intervals.	136·3	39·8	176·1	5·2	4·7	9·9	186·0	1·45	·056	·012	Acid reaction.
119	—	Same after treatment with two grains per gallon Ferrous sulphate ($FeSO_4 . 7H_2O$) and seven grains lime (CaO).	98·8	19·3	118·1	–	–	–	118·1	1·126	·045	0·75	Neutral reaction.
Reduction per cent.			28	51	33	100	100	100	36*	22	19		

* Most bleach works effluents contain more suspended matter than this.

Appendix 2.

It is here shown that all suspended matters are removed; the total dissolved solids reduced by 33 per cent., while the organic matter is reduced by 51 per cent.

In all the other cases, whether total dissolved solids were much higher or much lower, there was a marked reduction in both inorganic and organic matter.

In reply, then, to the questions asked *supra*, these figures and facts point unmistakably to precipitation being cheaper and more efficient than filtration, and I hope to be able to give details of a trial on a large scale, when the tanks now in progress at Messrs. Stanning's, Leyland, are completed.

B.—Dye and Calico Print Waste.

The foregoing analyses have shown calico, print, and dye wastes to be of a very objectionable character, too, and that they certainly demand treatment. Dr. Angus Smith showed that as a precipitant ferric chloride had a better effect on the colouration than ferrous sulphate (page 83, Report to the Local Government Board, 1882), and he also supplemented precipitation by aeration—with good results.

Dated August 12th, 1889, Mr. Hunt, F.I.C., Leeds, presented a Report to the Leeds Leather Trade Association, on "The treatment of the effluent from the Buslingthorpe Tannery, with special reference to a week's work at the Tanks," from which I am kindly permitted by the author to extract the following:—

"In your report of 8th May, 1888, a description of the tank is given. Since then an improved method of agitating the contents of the tank during precipitation, has been adopted. Perforated pipes have been fixed near the floor of the tanks. Through these pipes a strong current of air is forced by one of Meldrum's steam injectors. The air passing up through the water agitated it perfectly, and the process of precipitation is improved and shortened. The smell during precipitation complained of before is not now noticeable. Sulphate of iron (copperas) has been used for precipitating, a mixture of equal weights of copperas and alumino ferric cake giving good results."

More recently, 1892, Messrs. Mather and Platt, Salford, have brought out a similar arrangement for precipitating and aerating dye liquors, which I understand, has fulfilled all it was expected to do, with alumino ferric and lime as precipitating agents. The system of aeration has also been practised successfully by Messrs. R. A. Sanderson and Co., Galashiels.

In your laboratory at Preston experiments have been made on a small scale—and in the solution of this particular problem, namely, removal of colouration, a small experiment is quite as conclusive as a large one—with ferric chloride and lime, the results being eminently satisfactory. The colouration was *completely* removed after fifteen minutes aeration, the effluent resembling distilled water in transparency.*

The improvement in other respects can be noted from an analysis given below of the Whalley Abbey dye and print waste, before and after treatment. This sample is chosen as the one being most deeply coloured—reddish purple—and though it contains but a small quantity of organic matter and solids, if small quantities are affected the larger quantities are pretty safe.

* The addition of a little sulphurous acid has a good bleaching effect often—the acidity being afterwards neutralised by lime.

E. 2.—Analyses showing Result of Treatment by Lime, Iron Salts, and Aeration.

Number Sample.	Date.	Nature of Sample.	Dissolved Solids. Mineral.	Dissolved Solids. Organic.	Total Dissolved Solids.	Suspended Solids. Mineral.	Suspended Solids. Organic.	Total Suspended Solids.	Total Solids.	Organic Carbon.	Organic Nitrogen.	Free Ammonia.	Remarks.
135	9 Feb. 1893.	Print and Dye Waste, Whalley Abbey.	26·4	28·3	54·7	8·0	1·4	9·4	64·1	4·79	·425	·03	Slightly acid reaction.
120	—	Same after treatment with lime (CaO), ferric chloride (Fe_2Cl_6), and aeration.	28·2*	21·1	49·3	0	0	0	49·3	1·094	·042	·06	Neutral reaction.
Reduction per cent.			—	26	10	100	100	100	23	77	90	—	—

* More than *quantum suff.* of precipitant added.

I therefore beg to submit for your earnest consideration the advisability of recommending this course for manufacturers in the watershed, for the cost of running a small air compressor or Sturtevant blower is but small, and the removal of coloration from our rivers, would, in the eyes of the general public, cover a multitude of other sins, and at the same time certainly be an important step towards a more complete purification to follow.

The Disposal of Precipitated Sludge.

The volume of sludge arising from the use of iron salts and lime is greater than that from the use of many other precipitants. At Messrs. Stanning's, 60 gallons of liquor yielded with these agents 33lbs. of wet sludge—that is, about half-a-pound to a gallon, or about a ¼oz. of dry solids if the water be deducted, which amounts to 95 per cent. By the cautiously sparing use of precipitants these figures may be somewhat reduced, but not a great deal. Roughly speaking it will mean 4cwt. to 1,000 gallons treated, which is equivalent to some tons of sludge per diem in all cases.*

Manufacturers who have made a life-long study of the subjects upon which I have presumed to make as cursory remarks as possible, are fully cognisant of this fact, which, more than any other, I am inclined to believe is the stumbling block to the general adoption of precipitation. From correspondence with manufacturers up to the present it is to be gathered that the majority of them stand back on these grounds, while others have circumstantial reasons, and just a few still plead ignorance, thinking perhaps, that "where ignorance is bliss, 'tis folly to be wise."

Attempts have been made to utilise sludge for the manufacture of—

1.—Cement;

2.—Manure;

3.—Illuminating gas; and

4.—For fettling puddling furnaces.

In no cases as yet have the results been financially satisfactory, and in the fourth instance not satisfactory at all, the percentage of iron oxide in the sludge being too small.

Analyses of sludge from bleach liquor only, calico print waste only, and from the tanks of Woods', at

* Messrs. Stanning calculated independently that they abstract 5 tons per diem of dry solids from fabrics. This, amounting to 100 tons wet sludge, about coincides with the figures given above. Effluent 500.000 gallons.

Appendix 2

Brinscall, where logwood chips form a large proportion of the waste, have been made with results as follow:—

Series F.—Analyses of Precipitation Sludges well dried at 212° F.

——	134. Sludge from Woods', Brinscall (principally Logwood Chips) after Lime and Ferric Chloride.	133. Bleach Waste (Stanning's) Sludge after Lime and Iron Sulphate.	132. Dye and Print Water Sludge (Laboratory) after Lime and Ferric Chloride and aeration.
Moisture	1·09	2·31	2·52 per cent.
Organic Matter, CO_2 &c.	96·73	36·83	28·66 per cent.
Inorganic Matter	2·19	60·86	68·81 per cent.
Nitrogen, equal to Ammonia.	—	·004	Trace only.
Phosphoric Acid	—	·003	·001
Inorganic Matter. Iron Oxide (F_2O_3).	—	—	13·94
Inorganic Matter. Lime (CaO)	—	—	39·27
Inorganic Matter. Silica Alumina, &c.	—	—	6·43
Gases given off per ton of Sludge.	7,762 cubic feet.	1,794 cubic feet.	287 cubic feet.

Cement.

The manufacture of cement to stand the breaking tests of present day engineers is a difficult matter with the best materials in good condition, while with such sludges as those above quoted, where all the constituents of a good cement are not present, and where other substances, difficult to abstract, and which would have a deleterious effect upon the proper and useful constituents of cement are present, the difficulty is increased.

And in addition to the disadvantages of its wet condition and the additions or abstractions necessary, even if possible, such sludges could hardly compete with the raw material for cement making at present prices; for the prime cost of cement raw materials—lime-stone and clay—form only a small item in the cost of production, the rest being swallowed in burning.

Experiments are still being made with a much more likely material, namely, the sludge from Chance's Sulphur Recovery Process, which is considerably over 90 per cent. carbonate of lime, and until these have been brought to a successful issue there is not much hope for either sewage or manufacturers' sludge.

Manure.

The value and price of a manure are based upon the quantity of nitrogenous matter and useful phosphoric acid therein. In sewage sludges these fertilising agents sometimes amount to a quantity worthy of consideration; but in analyses given here they are the merest traces, and considering the source of the sludge no more could be expected.

Gas Making.

The poorest coal for profitable gas making must give off about 8,000 cubic feet to the ton, the best give about 15 to 18,000. None of the three sludges above approaches this figure, and in their raw state they cannot therefore be utilised for this purpose. That from Woods' at Brinscall comes nearer than the others, owing to the large amount of vegetable matter present. Practically the sample was logwood chips dried, but the amount of gas produced probably would not justify the laying down of gas and drying plant. The gas from this far exceeded in calorific value the gases from the other two samples of sludge, volume for volume. Just now it is being sold to a Manchester firm, which carbonises the woody matter, so obtaining pyroligneous acid, naphtha, pitch, and charcoal; but its value for this purpose is not more than nor even as much as that of wet sawdust, which could be similarly utilised, and, as a matter of fact, the price obtained barely covers carriage.

The case of Messrs. E. Schwambourne at Aachan is mentioned by Hummel, which deserves notice.

Here the refuse wash from raw wool, and the milling and washing of cloth, is precipitated by lime. The composition of air-dry precipitate is as follows:—

Water	3·11 per cent.
Lime and Ferric Oxide	18·47 „
Fatty matter	71·96 „
Waste Fibre, &c.	6·46 „

Mixed with coal, this precipitate serves for the manufacture of illuminating gas.

The mixture of lime soaps* from dye and print works with the sludge might be similarly tried, though it is questionable whether the fat and other combustible matter would reach 78 per cent. as in the case above, and much would depend also upon the price received for fat recovered, compared with the value of the gas made, after deducting working expenses and interest on plant capital.

The subject of sludge disposal, then, must here be left unsettled. It is a point for each manufacturer to settle for himself; but as there is nothing in it of much value, it is very questionable whether anything will ever be got out of it, and one is tempted to say "Ex nihilo nihil fit."

Comparisons cannot well be made with this and the recovery of sulphur, soda, or acid. Before such processes of recovery were invented, in the first of these cases all the sulphur used by acid or alkali makers was simply being thrown away with the waste (except that little left in pyrites clinker), and makers were of course forced to buy more at high prices to keep going. In the second case also, paper makers were throwing away soda and buying fresh. In the third, acid makers were sending up the towers or flues a proportion of the very acid they were making to put on the market.†

But there is no analogy between these and the case of precipitated sludge, which is exactly the dirt and refuse that has been in the way from the very beginning.

That a storage place, or a use for it cannot be found is no excuse for non-treament; for the object of the Joint Committee, as I understand, is only to see that such refuse is not brought from the four corners of the earth and thrown to stagnate along the bed of the river Ribble.

Grease Recovery.

It has been previously mentioned that certain colours are brightened by passing them through a solution of soap. This soap solution, after using, is in some cases thrown away, and in others attempts are made to recover the grease therefrom.

Soap is formed by the combination of a fatty acid with a base. The base may be an alkali, alkaline earth, or a mineral.

The fatty acids of a soap so formed may again be separated and recovered by—

First.—Treating the soap with an acid which has a greater affinity for the base than the fatty acid has, when of course these latter acids are liberated.

This is done in many cases. The soap liquors are run into tanks, mixed with hydrochloric or sulphuric acid, when the acid added forms a chloride or sulphate respectively with the base of the soap, and the fatty acids are liberated, rising to the surface, and may be skimmed off, or filtered.

This method is practised at the Whalley Abbey Print Company and Steiner's, Church, with the following result:—

* The lime from lime soaps would by this means be kept free of the rivers.

† Apart from this I am informed by a large firm of indigo users in the Ribble Basin that since increasing the size of the precipitation tanks, at the suggestion of the Joint Committee six months ago, they have saved an extra amount of indigo, value £400.

Appendix 2.

SERIES G. 1.—ANALYSES OF SOAP LIQUOR BEFORE AND AFTER TREATMENT BY ACID.

No.	Date.	Nature of Sample.	Parts per 100,000.				Parts per 100.	
			Suspended and Dissolved Solids.		Total Solids.	Grease (Fatty Anhydrides).	Acidity. Normal Caustic Soda required.	Alkalinity. Normal Sulphuric Acid required.
			Mineral.	Organic.				
156	8/2/93	Soap Liquor (Whalley Abbey P. Co.) before treatment.	264·1	578·8	842·9	386·8	—	·2
157	8/2/93	Same after treatment with Acid (HCl.)	62·8	811·3	874·1	4·0	10·5	—
152	16/2/93	Soap Liquor (Steiner's) before treatment.	94·0	166·3	260·3	152·4	—	·3
153	16/2/93	Same after treatment with Acid (HCl.)	160·5	388·2	548·7	220·0	·3	—
158	1/3/93	Thom's before treatment - -	68·7	231·6	300·3	76·4	Sample erroneously taken after being acidified.	
159	1/3/93	Same after treatment - -	60·2	124·5	184·7	28·8	·6	—

Second.—The fat may be recovered also by treating the soap with a second base, which has a greater affinity for the fatty acids than the base already combined with them, when a second soap will be formed, and, if insoluble in water, will form a precipitate that can be collected.*

The Rivers Pollution Commissioners reported as follows on treatment by the second method:—

"But the action of acid is not the only method by which this decomposition of the soap and the separation of the grease could be effected; for the soda of the soap it is possible to substitute other bases, such as lime or oxide of iron, and the lime or iron soap so produced is insoluble. We believe that lime has been proposed, if not used, as a means of treating the soap suds, but we have not heard that salts of iron have been thought of. If lime were employed it would be in a state of burnt lime made into a thin paste with water, known as 'milk of lime.' We have made repeated trials of lime in the laboratory, and can speak very favourably of the action. When added judiciously, and without excess, it causes a ready separation of the soap suds into clot and clear liquid, and the action is greatly aided by the addition of a small quantity of alum. . . . The magma separated from the soap suds by lime would not be greasy; it would be, as we before said, an insoluble soap. The liquid flowing away would be *alkaline* from free *soda*, not acid as it is by the present method; indeed, the rivers would be doubly benefited by the discharge of clear instead of foul liquid, a soft water instead of water laden with salts. The insoluble compound would require to be decomposed by acid subsequently, but this would be done by the extractor at his works, and under favourable circumstances, and *the sulphate of lime produced would not need to pass to the rivers.*

"The use of salts of iron for cleansing the soap suds might prove equally beneficial. Perchloride of iron in solution, added to the soap waters, produces a ready separation of the fatty matters, and a clean liquor for discharge. Sulphate of iron, or green copperas, which is largely used in the dying of black goods, is also available for this purpose. The iron soap produced would be subsequently decomposed by sulphuric acid, and the iron recovered as sulphate of iron for further use."

Lime is used in some cases in this watershed, in the manner just described, but the lime soaps formed are not sent away to the "extractor at his works," but are treated by acid on the spot, and the weak acid left, together with salts formed from this treatment, then mixed with the suds before liming, the consequence being that just the same amount of salt goes into the river as would be in case lime were not used at all, but acid only. Here, therefore, the statement in the extract printed in italics* is valueless, and, as a matter of fact, there is more chloride of lime† present in the effluent from Drew's, where lime is used and the grease afterwards recovered from the lime soap, than in the effluent from Thom's, where acid only is used.

* Soaps formed from fatty acids and soda or potash are soluble in water. Those formed from fatty acids and alkaline earths, or from acids and minerals, are insoluble in water.

* Not italicised in Report of Commissioners.

† Hydrochloric acid is used at Drew's, not sulphuric.

SERIES G 2.—FAT EXTRACTION BY LIME. ANALYSES OF SOAP LIQUORS BEFORE AND AFTER TREATMENT.

No.	Date.	Nature of Sample.	Parts per 100,000.				Parts per 100.	
			Suspended and Dissolved Solids.		Total Solids.	Grease (Fatty Anhydrides).	Acidity, Normal Caustic Soda required.	Alkalinity, Normal Sulphuric Acid required.
			Mineral.	Organic.				
148	6/2/93	Drew's Waste Soap Liquor before treatment.	32·0	552·3	584·3	312·0	—	·4
149	6/2/93	Same after treatment by lime, together with liquor from final fat extraction.	240·5	62·2	302·7	—	—	·2
150	16-17-18/2/93	Grafton's, before treatment.	56·1	113·9	170·0	16·81	—	·4
151	16-17-18/2/93	Same after treatment -	70·2	66·2	136·4	Trace.	—	·3

Appendix 2.

Messrs. Thom formerly used lime and alum, but have discontinued the practice in favour of acid only. The fats after being separated from the soaps by acid sooner or later, are caught by sawdust filters. The sawdust is then hot pressed and the exuded fat distilled to obtain olein, stearin, etc., for market.

The fats in the effluents above are due to ineffective filtering and bad management generally.

Series of Analyses G 2 shows the mineral matter in the effluent to go up, as would be expected from the addition of lime, and the organic matter to go down owing to loss of fat.

In the Series G 1 one would expect organic matter to go down and mineral matter to be only slightly affected, as the soda is simply changed from the base of one salt to the base of another. This expectation is realised with Thom's but not with the other two. At the Whalley Abbey Co.'s all solids are higher, but the fats reduced, while Steiner's tanks seem to offer a fair field for a soap or candle factory.

These discrepancies are explained by the following letters received:—

Whalley Abbey Printing Co., Limited,
Whalley, near Blackburn, March 10th, 1893.

Dear Sir,

The reason of the discrepancy between the amount of solid matter in the untreated soap liquor and that in the treated will be that they are two different liquors. When your man came I gave him some of the liquor that was being pumped up then, and also some of the treated liquor that had been standing several hours. Now this soap liquor may vary considerably in strength at different times, according to the class of goods that are being soaped, and for other reasons, and so the liquor may have been quite different to the one coming up at the time I took the samples. If you like I will take samples of the liquor coming up and also of the same after treatment and send them on to you. I should think, however, that this is scarcely necessary, as your analysis shows that we take the fat out of the water.

Yours faithfully,
ALFRED M. HANSON.

Church, Lancashire, 15th March, 1892.

Dear Sir,

Referring to your letter of the 8th instant and your representative's call on Monday last regarding same, we have made a careful examination of our filters, and find that they have become choked up with fat, etc., and this will account for the sample marked "after treatment" being so unsatisfactory as you report. We had not time to test the sample ourselves, otherwise we should have discovered the defect and explained sooner.

We are, however, having the filters reconstructed, and will communicate with you again on completion thereof.

As to your remark that your assistant was not allowed to see the samples taken, we would state that he merely asked for samples, and did not in any way indicate that he wished to see them drawn. If he had done so, we should only have been too pleased to let him see the samples taken.

Yours faithfully,
p. pro F. STEINER AND CO.,
GEO. E. UNTTEY.

IRON SALTS FOR THE RECOVERY OF GREASE.

There is no case in the Watershed where the suggestions of the Commissioners have been followed with respect to the employment of iron salts. This is probably due to the cost as compared with lime or acid.

From experiments with small quantities of soap liquor from Drew's, it is questionable whether the results as given below justify the increased expenditure, especially as upon this recommendation it is not "soft water instead of water laden with salts," but water laden with salts just as though acid only had been used that enters the river. An experiment on a large scale would be interesting.

Series G 3.—FAT EXTRACTION BY IRON SALTS.

No.	Date.	Nature of Sample.	Parts per 100,000.				Parts per 100.	
			Suspended and Dissolved Solids.		Total Solids.	Grease (Fatty Anhydrides).	Acidity, Normal Caustic Soda required.	Alkalinity, Normal Sulpuric Acid required.
			Mineral.	Organic.				
148	6/2/93	Drew's before treatment -	32·0	552·3	584·3	312·0	–	·4
154	6/2/93	Same after treatment by ferrous sulphate.	*281·0	69 7	350·7	Nil	- - Neutral.	
155	6/2/93	Drew's after treatment by ferric chloride.	*185·9	62·4	248·3	Nil	- - Neutral.	

* More than *quantum suff.* of precipitant added.

In the analyses of all effluents from grease recovery processes, it will be noticed that though much of the grease is recovered there remains a large quantity of other solids, more than in some of the works general effluents, and yet in only one instance (Whalley Abbey Print Co.) is any attempt made to treat these effluents further. Their nature should make further treatment by precipitation and aeration imperative, as in all cases they are discoloured also.

The method of grease recovery to benefit the river most appears to be:—

1. Treatment by lime.
2. Exportation of lime soap.
3. Precipitation and aeration of extraction tanks effluent.

Aeration pipes in the extraction tanks would almost pay for themselves in increased efficiency of mixing by means of air.

THIRD.—PAPER MANUFACTURE.

The basis of all papers is vegetable fibre or cellulose, and the object of the paper-maker to divest vegetable growth, esparto grass, linen cuttings, cotton rags, ryegrass, hemp bagging, straw, tarpaulin, ropes, peat, etc., from any other matters associated with this fibre or cellulose. Such associated matters are resins, gums, silicious coatings, fats, oils, and very largely adventitious dirt.

The process is briefly:—

1. Dusting and picking—refuse solid.
2. Boiling raw stuff with caustic soda, to saponify fats, vegetable oils, and resins—soda recovered.
3. Washing raw stuff after boiling with caustic soda, now termed half-stuff—soda recovered.
4. Breaking up half-stuff to pulp and washing in breaking engine—effluent wash water goes to river.
5. Bleaching the washed and broken half-stuff in poacher (or by means of chlorine gas)—bleach liquor used over again if chlorine is not all liberated, otherwise goes to river.
6. Beating bleached stuff to a pulp by means of beating engines, and washing further—effluent goes to river.

7. Passing pulp (after sizing, colouring, and loading) through paper making machine in which it is strained, layered, rolled, and cut, emerging as paper—water from paper machine used over again continually.

In examining the effluents from these processes the spent soda (2 and 3) may be left for the present as it may and ought to be recovered, except perhaps in the cases of mills making brown or shop papers exclusively, where only a small quantity is used. Effluents from 5 and 7, it will be seen, are used over and over again, thus leaving only the wash waters from breaking engines (4) and beating engines (6) to be dealt with, as that from 1 is solid.

Appendix 2.

The effluents (4 and 6) are always more or less foul, depending upon the material in hand and, of course, the particular point of time in the washing process, the machines running generally about one or two hours.

Samples of machine effluents were taken on Friday, 9th March, from Messrs. Dimmock's, Darwen, their natures being depicted below:—

Series H.—Analyses showing Solids in Paper Mill Wash.—Parts per 100,000.

No.	Date.	Nature of Sample.	Dissolved Solids. Mineral.	Dissolved Solids. Organic.	Total Dissolved Solids.	Suspended Solids. Mineral.	Suspended Solids. Organic.	Total Suspended Solids.	Total Solids.
160	9/3/93	Samples from beating and washing machines taken every five minutes and mixed.	152·2	110·5	262·7	32·1	63·9	96·0	358·7
161	9/3/93	Samples from breaking and washing machines taken every five minutes and mixed.	18·6	18·3	36·9	8·1	29·8	37·9	74·8

These effluents are subject to the same remarks as bleacher's uncoloured effluent in the main, and certainly so far as treatment is concerned.

Upon being mixed with iron sulphate and lime a decided deposition of solids takes place quickly and a clear supernatant effluent is obtained. If such treatment and the recovery of soda were insisted upon, the river Darwen would soon present a very altered appearance for the better.

Soda Recovery.

Just as the dyer adds an excess of colouring matter in the becks over what is required for absorption by the fabric, so does the paper-maker add an excess of soda in his boiler, and to the same end, namely, acceleration of the action desired, and thus a saving in the cost of running machinery and an increased output. But this excess of soda added is something very considerable. The strength of the caustic lye first added is about 10° Twaddell, is reduced in boiling to about 4° Twaddell, and then further reduced to 2° by the addition of wash water.

A sample of waste soda lye and wash waste at 2° T. from Dimmock's, March 9th, 1893, contained 145grs. per gallon of soda. This soda is of course in solution, and side by side with other foreign matters both in solution and suspension. It can be recovered by evaporating the water and burning off the foreign matter from the residue after evaporation.

An evaporator cannot be judged efficient or otherwise according to the amount of soda put out. This depends upon the amount and strength of the soda ash primarily placed in the causticiser, and also upon the nature of raw materials boiled. Such materials as flocks and rags, containing comparatively large quantities of fatty matters, take naturally more soda, weight for weight, than straw and esparto, for saponification.

The percentage of soda in the ash recovered also must depend upon the amount of dirt and fibre in the waste liquor, these latter being more abundant in liquors from the boiling of flocks, rags, and bagging, than in those from the boiling of straw, esparto, or grass.

Hence a very efficient evaporator may be running nearly at a loss in one mill and a less efficient evaporator making a profit at another, though both are very important factors in the prevention of rivers pollution.

Many different methods of evaporation are practised, but the most recent and perhaps the most scientific is the "Chapman."

The distinguishing feature of this evaporator is that the liquors are evaporated at a reduced pressure or partial vacuum maintained by an air pump. This partial vacuum lowers the boiling point of the liquor. Further, it is claimed that the air pump and all other incidental pumps or machinery are run by power raised from steam generated by the liquor itself, which is first run into a steam boiler.

At Messrs. Dimmock's it was found the generation of steam from the liquor itself was a failure, as the excessive incrustation in the boiler brought down the flues. There is more than the usual amount of fibre in Messrs. Dimmock's waste lye.

On testing the evaporator March 9th, 1893, the strength of liquor running into pans was 2° Twaddell, at a temperature of 90° F., and contained 145 grains of soda per gallon.

The strength of the liquor running out of the pans was 42° Twaddell, at a temperature of 100° F., and contained 5,600 grains of soda per gallon.

From Messrs. Dimmock's weekly return* ·276 tons of coal are used per hour in the furnaces for incinerating the liquor after evaporation, but for running the evaporators three small engines were required.

The first, for pumping liquor into pans, of which the I.H.P. on date of trial was 2·1.

The second, for maintaining vacuum in pans, pumping water for condensing purposes, etc., I.H.P. 35·3.

The third, for pumping liquor from evaporating pans into incinerating furnaces, I.H.P. 2·3. Total I.H.P., 39·7.

Coal used per hour at 4lbs. per I.H.P. equals 158·8 lbs. per hour. This gives for the whole of the plant ·283 tons of coal per hour, or 4,155 gallons of liquor per ton of coal. It also brings up the total coal used per 122 hours (see Messrs. Dimmock's return) to 34·5 tons, or one ton of ash per 3·45 tons of coal.

One ton of ash before being used is valued at £5, but the recovered ash is one-third below strength in this case.

To the matter given above must be added the interest on capital for plant, depreciation and running expenses, the profit or loss depending, as before pointed out, upon the nature of initial waste liquor. The figures given, too, are to be taken for purposes of this report, and not as a strictly scientific calculation, upon which the system may

* One Week's Working Averaged.

Time.	Strength.	Total galls.	Coal.	Ash recovered.
122 hours	Twaddell at 60° F. 6 in, 44 out.	143,565	33·75 tons	10 tons.

Appendix 2.

be condemned or otherwise in comparison with any other.*

Nevertheless, it can easily be calculated from these data that this "Chapman" evaporator is strong in the pans but weak in the incinerator or roaster.

It is very important that an incinerator be laid down on the best possible lines, for the denser a liquor becomes, the more the heat required to evaporate a given quantity of waste from it. I have italicised the latter portion of Mr. Goodall's statement to illustrate this point.

Another popular form of evaporator is the "Porion," now in use at Messrs. Peebles', Rishton, a detailed description of which accompanies this report, as one also of the "Chapman." As an incinerator pure and simple it is questionable whether there is anything at present to beat this, though in the earlier stages no advantage is taken of the diminished temperature at which all liquids boil *in vacuo*. The two compare thus:

—	Tons of coal per ton of ash recovered.	Gallons of liquor per ton of coal.
Chapman (Dimmock's)	3·45	4,155
Porion (Peebles') -	1·6†	2,498

Seeing then that one is weak where the other is strong, and *vice versâ*, the most reasonable course appears to be a combination of the two, each at a reduced size.

There are no figures given in Mr. Davis's paper on the Porion evaporator, read before the Scottish Paper Makers' Association, November, 1888, from which the amount of coal can be calculated which would be required to reduce liquors from, say, 2° T. to 40° T. (100° F.), the point at which they virtually enter the incinerator proper, nor do I know of any means whereby this could be calculated in practice, for it would probably be contended that the reduction was brought about by waste heat in the Porion. But the tendency will be to make liquors weaker and weaker by washings in the future, to prevent river pollution, and it appears to me that a point may be reached beyond which it would be more economical to resort to multiple effect evaporation for the earlier stages, than to extend the evaporating end of the Porion to a point where it would be almost cold. This is evidently Mr. Davis's opinion as expressed in the paper referred to above:—

"In the early days of soda recovery the lyes evaporated in paper mills and other factories were very strong, the weaker liquors being turned into the nearest streams, but the continual desire to prevent the pollution of our rivers has led to weaker lyes being evaporated. The subject comes to us therefore under a new set of conditions. Manufacturers may be inclined to ask whether these altered conditions have changed our views with regard to the efficiency of the Porion system? Our reply will, we hope, be clear and definite when we say, *Give a Porion evaporator liquor at 10° Tw. and 100° F. and it will 'beat the record,' for profit, of any existing evaporator.* If there is any merit in multiple evaporation, and we believe there is, *up to a point*, it would be in so arranging the plant that all the strong liquor is treated direct in a Porion, the weaker liquids being concentrated to 10° Tw. at 100°. F., and then handed over to the Porion to finish.

"Under any system of recovery, furnaces, or calciners, are required: the Porion chamber is simply an addition to these, and is by no means costly in itself, and will stand for many years without repairs. Multiple evaporation has been heretofore clouded with too many specious statements; it is too often overlooked that expensive furnaces are required beside the multiple-effect stills and the steam boilers necessary to supply them with steam. Nevertheless, it is often a decided economy to employ multiple effect stills, as we have said before, up to a certain point, and that point is a concentration to 10° Tw. at 100° F."

Weekly statement from Peebles' *re* Porion evaporator:

Time.	Strength.	Total galls.	Coal.	Ash recovered
132 hours	Twaddell at 113°F. 6·2.	46,962	18·8 tons	11·05 tons.

But whatever system of evaporation be adopted, that soda can be recovered without financial loss and that no hardship would be endured by any manufacturer if this were insisted upon, has been, I think, fully proved.

EXTRACT FROM "WATT ON PAPER MAKING" (p. 49).

"The liquor resulting from the boiling of esparto, which is of a dark brown colour, contains nearly all the soda originally used, but it also contains silicious, resinous, and other vegetable matter which it has dissolved out of the grass, the silica taking the form of silicate of soda. The esparto liquor, which was formerly allowed to run to waste, polluting our rivers to a serious extent, is now treated by several ingenious methods for the recovery of the soda, with considerable advantage alike to the manufacturers and the public. The process consists essentially in boiling down the liquor to dryness and incinerating the residue. During the process of incineration, the carbonaceous matter extracted from the grass is converted into carbonic acid, which, combining with the soda, re-converts it into carbonate of soda, which is afterwards causticised with lime in the usual way, and the caustic soda thus obtained is again used in the boiling of esparto. Although one or other of the recovery processes is adopted at a good many of our paper mills, the recovery of soda is by no means universal as yet, but the time will doubtless soon arrive when the economical advantages of the process will be fully recognised. Indeed, we know it to be the fact that some manufacturers are watching, with keen interest, the progress of some of the newer systems of soda recovery, with the full intention eventually of adopting one or other of them."

The return appended has been supplied by papermakers in the Ribble Basin. The names of firms are not given, as the information was to be considered private in some instances. Additions have been made since the return issued in March, 1892.

FOURTH.—TANNING.

As, up to date, only four tanneries have been reported in the district, draining into natural watercourses directly, and as one of the these is to be coupled up with sewers under an order of the County Court, it will not be requisite that a complete account of the trade should be detailed.

Suffice it to say that the refuse from tanneries is of a highly offensive character, due to the animal matter it contains from the washing and soaking of skins.

"Beside considerable quantities of ammonia, old limes contain tyrosin, leucin or amidocaproic acid and some caproic acid, the disagreeable goaty odour of which is very obvious on acidifying an old lime liquor with sulphuric acid, by which considerable quantities of a partially altered gelatin are at the same time precipitated. Very old limes, especially in hot weather, often contain active bacteria, which may be seen in the microscope under a good $\frac{1}{4}$ inch objective. Their presence is always an indication that putrefaction is going forward. . . . It is probable that in many tanneries the ammonia would pay for recovery from the lime liquors, which would be easily done by steaming the old limes in suitable vessels, and condensing the ammoniacal vapours in dilute sulphuric acid. (Some appliances suitable for this purpose are described in the Journal of the Soc. of Chem. Industry, III., 630)."

H. R. PROCTOR, F.C.S., on Tanning.

* Mr. Goodall, the Manager of Hendon Paper Works, Sunderland, gives the following particulars of the actual work performed by a Chapman evaporator: — 200,000 gallons of black liquor of $5\frac{3}{4}$ T. at 160°F. are reduced to 29,370 gallons of thick liquor of $46\frac{1}{2}$T. at 125°F. ready for the roasters, by an expenditure, of 20 tons 11 cwts. 3 qrs. of small coal, equivalent to an evaporation of 37 lbs. of water per pound of coal used, and to $10\frac{1}{2}$ cwt. coal per ton of ash recovered, *without counting the coal used at roaster.* (Own italics.)

† In comparing these figures it is very important to note the difference in strengths of initial liquor. There is apparently no wash water admitted at Peebles, and esparto is the principal raw stuff.

Appendix 2.

The Rivers Pollution Commissioners reported:—

"The waste liquors from tanneries may, for all practical purposes, be regarded as concentrated sewage, possessing from five to ten times the manure value of the latter. These liquors would, therefore, form an acceptable contribution to the contents of town sewers, when the sewage is applied to irrigation. If this were impracticable, owing to the tannery being situated in the country, there could be no difficulty in disposing of these valuable liquids upon the neighbouring land. Or, lastly, they might be sufficiently purified to be admissible into streams by downward and intermittent filtration through sand or porous soil."

There is just a possibility of the three remaining tanneries being connected with town sewers (Colne), but if this is not done, precipitation and filtration should certainly be resorted to.

Fifth.—The Manufacture of Alkali and Various Chemicals.

Other than solid refuse the only polluting agents from alkali works is the drainage from old waste tips. Quoting from my report in May last, page 8, Proceedings Ribble Joint Committee:—I cannot do better than quote from the report of Mr. Fletcher, Chief Inspector to the Local Government Board, under the Alkali Works Regulation Acts Report for the year, 1888, to the Chief Secretary for Scotland.

"The 'tank waste' or 'vat waste' of the Leblanc process is the residuum after the lixiviation of the 'black ash' or crude soda. It consists mainly of calcium sulphide, and is liable to oxidation and a decomposition, which causes the generation of sulphuretted hydrogen, so that the material, unless protected from the air, speedily becomes highly offensive. As, moreover, this waste is produced in large quantities, there has always been great difficulty in disposing of it. In the neighbourhood of some alkali works it is to be seen in almost mountainous masses, occupying valuable space, and if not giving off offensive gases, yet yielding a drainage which is a source of great nuisance."

This waste contains about 15 per cent. sulphur when fresh from the lixiviation tanks, but important changes take place when left exposed to the atmosphere. It is now about 20 years since the finishing touch was given to this tip in the shape of a covering of soil and crop of grass. Meanwhile most of the sulphides have drained away into the brook, and portions are so continually draining into it, either as sulphides or other soluble sulphur compounds. But in whatever form the sulphur enters, a nuisance is bound to be created, for the Douglas at this point holds in solution an extraordinary amount of carbonic acid, due to the decomposition of unpurified sewage or sewage effluents from Horwich, Blackrod, Adlington, Ince-in-Makerfield, Standish, Aspull, Pemberton, Billinge, and other centres of population higher up. The drainage also contains sulphydrates and sulphides, as well as hypo-sulphites, and though in small amounts (only ·1 per cent. of the former, and ·06 per cent. of the latter), in amounts sufficiently large to be far too perceptible.

The action of the carbonic acid on sulphydrates and sulphides of lime is to produce sulphuretted hydrogen and carbonate of lime; on hypo-sulphites, sulphurous acid is generated and sulphur precipitated.

The result is that the river on nearing the drainage outlets is turned milky white, in its ordinary course, and in the absence of this drainage in dry weather the diminished volume of the river is blackened by unpurified sewage and manufacturing refuse.

It is therefore very desirable that steps be taken to prevent the entrance of this liquor into the river, though it is not sufficiently rich in sulphur to pay for its recovery. Its strength is less than 1° Twaddell, whereas liquors similar in other respects, but of 5° or 6° Twaddell, are permitted a second percolation through the heap for concentration, before being used in the Chance Claus process, and then not for recovery directly but only instead of water for lixiviating fresh tank waste, to go into the carbonators.

There are, nevertheless, means available whereby this drainage can be rendered harmless, and since the pollution may continue many years under present circumstances (a sample of the waste contained ·2 per cent. of oxidisable sulphur only 2 feet from the surface) some means should certainly be adopted.

Sample 21. Analysis of Tank Waste on Canal Embankment and Banks of Douglas at Parbold. Taken at a depth of 2 feet. April 20th, 1892.

Moisture at 212° F.	45·924
Sand	4·384
Carbon	2·326
Silica (combined)	0·782
Iron Sulphide	2·039

Carbonic Acid in Solution in River Douglas.

Sample No.	Point.	Total Dissolved Gases at Normal Pressure and Temperature.	Carbonic Acid in Total Gases.
30	Source above Horwich.	19·5cc. per litre	0·98cc. per litre.
31	Near Alkali Tip at Newbold.	19·7cc. per litre	5·6cc. per litre.

The yellow liquor (Sample 22) could be treated by Chance's process of sulphur recovery, though not with any hope of profit, for since the total oxidisable sulphur amounts to only 125·8 grains per gallon, 120,000 gallons would need treating to obtain a ton of sulphur, value five pounds. To carry by rail 120,000 gallons weighing 500 tons to the nearest plant is out of the question, while the suggestion of putting down plant on the spot to treat a liquor limited in quantity and continually decreasing in strength is still more absurd.

But it might be treated with little and gradually decreasing cost by means of ferric chloride. If this salt be added to the liquor, a precipitate of iron chloride is formed, which could be collected and sold to sulphuric acid makers, and the clear liquor run into the rivers. No disagreeable smell accompanies this treatment as at present exists, and the amount of ferric chloride necessary for treatment would diminish with the diminution of oxidisable sulphur in the liquor, and in time die out altogether.*

Alkali drainage might also be used as depilatory in the process of tanning in virtue of the sulphides present, for although small in quantity they could be brought up to strength. At one time sodium sulphide was made from tank waste by Messrs. Gamble, St. Helens, under Schaffner and Helbig's patents, but I cannot say whether this has been recently discontinued in favour of the recently invented Sulphur Recovery Process.

The Hyndburn Brook, at Church, is banked on both sides by high masses of alkali waste, tons of which are continually falling into it. The drainage from this tip emits large quantites of sulphuretted hydrogen, especially when entering the brook and coming in contact with the acid bleach waste from about eight or nine works less than two miles away up stream.†

* Iron salts in almost any form might be used. Mr. Ballard, Inspector of Alkali Works, informs me that were it not for iron salts draining into the Sankey Brook, at St. Helens, that now famous stream would be in a much worse condition than it is even.

† A bleaching mill formerly running close to the river was shut up, owing to damage to fabrics by machinery marks. The machines were attacked by gases arising from brook.

Appendix 2

VARIOUS CHEMICALS.

Soap.

As mentioned earlier, common soap is a combination of alkali and fatty acid.

The soap-boiler boils alkali and neutral fat—*not fatty acid.* A neutral fat consists of a fatty acid in combination with glycerin. When, therefore a neutral fat is boiled with an alkali soap is formed, by the combination of alkali and fatty acid, while the glycerin is left in the mother liquor.

In order to effect the readier separation of soap from the mother liquor common salt is added. This mother liquor may contain, according as to whether white or black soda ash used :—

Glycerin, common salt, sulpho-cyanides, cyanides, sulphides, albuminous, resinous, fatty, colouring, and other organic matter. On a large scale the glycerin is recovered, but it is not at present in the smaller soap factories. The number of these in the Ribble basin supplying soap to the print mills and cotton mills for size is very considerable, the effluents therefrom being, to say the least, most abominable.

For making the cheaper class of soaps dirty raw materials are often used, the dirt from which, for the most part, enters the river with the mother liquor.

"From soap factories there issue as refuse waters the mother liquors (*unterlaugen*, lit. under lyes) which remain at the unsalting of the curd, and which contain in the main common salt, glycerin solution, with generally a small quantity of caustic soda, the exact quantity of which has already been fixed by the economy of the factory management. A soap factory which produces daily 500 kilos of curd soap, supplies about 2 c. metres of lyes as refuse which may contain from 5 to 20 per cent. common salt."—(Fleck, 12th and 13th reports of the "Chemischer Centralshelle Zu Dresden.")

Sample of mother liquor entering Hyndburn Brook from H. Bury, jun., and Co., Church, 10/3/93, No. 162 :

Organic matter	6,232·0 parts per 100,000,	or 6·2 per cent.
Mineral matter	8,810·0 ,, ,,	or 8·8 ,,
Total solids	15,042·0 ,, ,,	or 15 ,,
Caustic soda	120·0 ,, ,,	or ·12 ,,
Glycerin	1,009·0 ,, ,,	or 1 ,,
Fat	6,984·0 ,, ,,	or 6·9 ,,
Chlorine, equal to common salt	5,302·0 ,, ,,	or 5·3 ,,

A fatty scum often arises from the soap pans in emptying mother liquor, which is skimmed into a tank and allowed to drain.

Sample of such drainage from H. Bury, jun., and Co., Church, 2/3/93, No. 163 :—

Organic matter	242·0 parts per 100,000.
Mineral matter	532·0 ,, ,,
Total solids	774·0 ,, ,,
Fatty anhydrides	1,272·0 ,, ,,

Tallow, Machine Oil, Waggon Grease, etc.

Suet, tripe cuttings, slaughterhouse offal, and other substances containing fat are boiled with acid, when the fatty acids rise to the surface, leaving below a very foul liquor for an effluent.

Sample from Bridge, Baron, and Co., Church, 10/3/93, No. 164 :—

Mineral matter	1,682·0 parts per 100,000.
Organic matter	4,514·0 ,, ,,
Total solids	6,196·0 ,, ,,
Acidity	12 parts per 100 Normal Soda required.
Fatty anhydrides	1,166·0 parts per 100,000.

Effluents from three last-named processes should be freed from any unused fat, soda, or acid in working, and afterwards treated by precipitation and filtration.

Preparation of Indigo Extracts.

Different preparations of indigo are made for use in different mills, chiefly by means of acids. For example, sulpho-purpuric acid or indigo purple is made by mixing indigo and sulphuric acid and heating the mixture, after which the purple is precipitated upon mixing with water. It is then filtered through cloths and washed with weak hydrochloric acid.

Filtrate from H. Bury, Jun., and Co., Church, 10/3/93, No. 165, gave—

Mineral matter	1,816·0 parts per 100,000.
Organic matter	1,798·0 ,, ,,
Total solids	3,614·0 ,, ,,
Acidity	9 parts per 100 Normal Soda required.

This effluent ought to be neutralised and submitted to precipitation and filtration.

An agent could probably be found which would neutralise and precipitate at the same time. There are many other obnoxious chemical effluents entering the river from tar distilleries, glue works, etc., space for the consideration of which cannot be found here, but which can be dealt with later, on their merits.

General Solid Refuse.

At Messrs. Blythe and Co.'s, Church, zinc chloride, for size, is made by dissolving zinc in hydrochloric acid. Any iron in the solution is liberated as oxide by means of chlorate of potash, and when so liberated is skimmed off and allowed to run into the river.

This might be dried and sold as a pigment. The same thing occurs in the manufacture of zinc sulphate.

I have also seen in various towns thrown on to the river bed, lime from cauticisers, chloride of lime dregs from making bleaching solutions, carbonised matter from soda recovery incinerators, calico printers' waste thickenings, pickings from esparto, tub washings, rubbish collected by water wheel screens, and even precipitated sludge.

It is a very difficult matter to trace these acts of misdemeanour right home. They are the work of a moment only, and though some good may be done by making an occasional example, it is a question whether the practice can be stopped except by moral suasion.

More I think could be accomplished by asking the manufacturers to meet the Committee to discuss these matters, and to co-operate with the Committee, all working from one centre.

Certain points are often raised, such as the building of retaining walls jointly, acquisition of land, the formaton of contributory areas, the adoption of standards, power of entry, the meaning of innocuous discolorations, etc., which want thoroughly thrashing out, and before any further steps are taken with the notices given, I would suggest that the parties concerned be asked to meet the Committee and state their views.

I cannot conclude without expressing my obligation to the firms mentioned in the Report for the samples supplied, and for the very kindly spirit in which they have assisted with any information asked for in connection with it, often with a great amount of trouble.

The following firms have also supplied samples, etc. :

Messrs. The Spring Valé Paper Company.
,, ,, Star Paper Company.
,, ,, Sabden Print Company.
,, W. N. Wilson and Sons.
,, John MacKenzie and Co.
,, Riley and Co., Hapton.

I am, Gentlemen,
Your obedient servant,
Wm. Naylor.

APPENDIX No. 3.

Handed in by Mr. R. A. Tatton, M.I.C.E.

MERSEY AND IRWELL WATERSHED.

Particulars as to the methods of Sewage Treatment adopted by the Local Authorities in the Mersey an

Note.—The samples have been taken over a period of two years, 1897-98

NAME OF AUTHORITY.	Population.	Population connected up. 1.	Estimated Quantity of Sewage in 24 hours. 2.	Character of Trade Waste in Sewage. 3.	Number of Precipitation Tanks and Total Capacity. 4.	Precipitant used. 5.	Quantity of Precipitant used per Week. 6.	Number of filters and Total Area. 7.
CHEMICAL PRECIPITATION ALONE.								
(A) Domestic Sewage only.								
Milnrow Urban District Council	8,600	8,000	About 200,000 gallons.	—	3 tanks, each 100ft. by 30ft. by 6ft. Total capacity, 337,500 gallons.	Alumina ferric	5 to 7 cwt.	—
(B) Sewage Mixed with Trade Waste.								
Bolton Corporation	115,000	130,000 (Borough, 115,000; rural, 15,000.)	5,000,000 gallons	1 tannery, 9 breweries, 2 dye works.	2 detritus tanks, 2 settling tanks. Total capacity, 4,000,000 gallons.	Lime, alumina ferric.	Lime, 28 tons; alumina ferric, 8¾ tons.	None
Manchester Corporation	536,000	514,960	About 22,000,000 gallons.	Print works, dye works, bleach works, brewery, tanneries, chemical works, galvanising works.	11 tanks, each 300ft. by 100ft. by 6ft. (average depth). Total capacity, 12,375,000 gallons.	Milk of lime and solution of copperas.	50 to 70 tons of copperas, and from 60 to 100 tons of lime.	None constructed at pre sent, with the exceptio of some small experimen tal filters.
Salford Corporation	198,000	198,000	Dry weather flow, 9,000,000 gallons.	Dye works, bleach works, breweries, print works, paper works.	12 tanks, each 110ft. long by 77ft. wide. Total capacity, 5,250,000 gallons.	Lime	About 80 tons	Filtration works are nov in course of constructior
Whitefield Urban District Council	5,800	5,000	Average 350,000 gallons per day.	4 dye works, 1 brewery.	10 tanks. Total capacity, 140,000 gallons.	Alumina ferric	Average 1 ton	—
Kearsley Urban District Council	8,000	6,370	127,400 gallons	2 dye works	3 tanks, each 89ft. by 35ft. by 5ft. 9in. Total capacity, 335,811 gallons.	Alumina ferric	About 9 cwt.	6 filters. Total area, 48 square yards; 261 gallon per square yard.
Farnworth Urban District Council	23,758	23,158 (All connected, except 600 rural.)	About 560,000 gallons dry weather flow.	1 dye works, 1 brewery.	3 tanks, each 160ft. by 50ft. by 9ft.; 2 tanks, each 100ft. by 28ft. by 9ft. Total capacity, 1,665,000 gallons.	Lime and sulphate of iron.	About 5½ tons per week.	None
Prestwich Urban District Council	10,469	8,000	452,504 gallons	2 dye works	9 tanks. Total capacity 606,010 gallons.	Alumina ferric	1 ton 6cwt. 3qrs.	4 filters. Total area, 92 square yards; 489 gallon per square yard.
PRECIPITATION AND ARTIFICIAL FILTRATION.								
(C) Chemical Precipitation and Rapid (Mechanical?) Filtration.								
Domestic Sewage only.								
Ashton-in-Makerfield Urban District Council.	900	900 (Including 156 from adjoining district of Abram.)	Quantity varies from 5,000 to 15,000 gallons.	—	3 tanks. Total capacity 15,000 gallons.	Alumina fer.ic	140 to 200lbs.	3 filters. Total area. 3 square yards; 285 gallon per square yard.
Atherton Urban District Council (Glasshouse).	16,500	7,500	66,000 gallons	—	3 tanks. Total capacity 426,000 gallons.	Lime and alumina ferric.	17·05cwt. of lime and 4·45cwt. alumina ferric.	None
Atherton Urban District Council (Hindsford).		6,800	60,000 gallons	—	6 tanks. Total capacity 210,000 gallons.	Lime and sulphate of iron.	3½cwt. sulphate of iron and 1·05cwt. of lime.	Total area, 100 squar yards; 600 gallons pe square yard.
Cheadle and Gatley Urban District Council.	8,200	6,000	About 200,000 gallons.	—	6 tanks. Total capacity 222,000 gallons.	Alumina ferric	Average 16cwt. 1qr.	Total area, 320 squar yards; 625 gallons pe square yard.

Note.—The term rapid filtration implies that the liquid is not held up in the filters over lengthened periods, as is the case with the biological filters, but is passed more or less rapidly through them.

APPENDIX No. 3.

Handed in by Mr. R. A. TATTON, M.I.C.E.

MERSEY AND IRWELL WATERSHED.

Irwell Watershed, derived from information supplied by the Authorities to the Joint Committee.

The limit of impurity is one grain per gallon of oxygen absorbed in four hours.

Depth and Character of Filtering Material. 8.	Method of using Filters (whether Intermittent or Continuous). 9.	Area of Land used for Filtration or Irrigation. 10.	Rate of Filtration in Gallons per Acre. 11.	Additional Area of Land owned but not used for Filtration. 12.	Sludge: How Disposed of. 13.	Number of Samples Below Limit.	Number of Samples Above Limit.	Total Samples.	Percentage of Samples Below Limit.	REMARKS.
—	—	7½ acres, only lately brought into use.	—	1½ acres - -	On land - - -	–	6	6	100	When the samples were taken, only a small proportion of the sewage was connected to the works.
None - - - - -	—	150 acres being now laid out into filtration plots. Subsoil land, loam, sand, and gravel, and land drained 6ft. deep. Plots to be worked intermittently.	—	—	Air-dried, and given away to farmers and others.	7	-	7	-	Samples are from tank effluent. Under an order of Court to construct further filtration works.
—	—	26¼ acres - - -	—	139¼ acres, including site of buildings, tanks, roadways, &c.	Sludge taken out to sea	29	–	29	–	Under an order of Court to construct further filtration works.
—	—	—	—	Total area of site, 34 acres.	Sludge taken out to sea	28	–	28	–	Under an order of Court to construct further filtration works.
—	—	3½ acres in course of preparation for use as filters.	-	1½ acres, on which are the tanks, buildings, &c.	—	3	4	7	57	-
2ft. 9in. of coke and cinders.	Intermittent -	Not yet in use - -	1,263,240	—	Given to farmers - -	4	2	6	33	The samples were taken before the filters were brought into use.
—	—	None - - - -	—	Total area of land at works, 10¾ acres.	Carted away by farmers	9	–	9	–	A scheme is before the L. G. B. for filters.
1 filter, sand, cinders, and stone. 2 filters, cinders, 3ft. deep.	Continuous - -	None - - - -	2,366,760	None - - -	Taken away by farmers	3	3	6	50	The samples were taken before the filters were brought into use.
Total depth about 3ft., made up as follows:—12in. sand, 12in. sand and polarite equal parts, 5in. sand and 4in. gravel, 3in. stone and agricultural tiles.	Intermittent -	About 4 acres; 2,500 gallons per acre.	1,379,400	- -	Used on the land by the farmers.	1	4	5	80	—
—	—	½ acre - - -	132,000	—	Carted away by local farmers.	–	4	4	100	These outfalls have been done away with, and the Atherton sewage taken to the Leigh works.
Gravel and sand, 2ft. 6in. deep.	—	1½ acres; 40,000 gallons per acre.	2,904,000	-	Carted away by local farmers.	4	1	5	20	
Sand, gravel, and polarite	—	The effluent is at times pumped on a plot of about 4½ acres of gravel land; 44,444 gallons per acre.	3,025,000	--	Pressed, and removed by local farmers, who take it readily.	-	11	11	100	—

Appendix 4.

APPENDIX No. IV.

PARTICULARS as to the METHODS OF SEWAGE TREATMENT adopted by the LOCAL AUTHORITIES in the WEST RIDING OF YORKSHIRE.

Sewage Disposal Works in the West Riding of Yorkshire. (Particulars furnished by the Sanitary Authorities except where otherwise stated.)

West Riding Rivers Board, H. MACLEAN WILSON, Chief Inspector.

SETTLEMENT OR CHEMICAL PRECIPITATION FOLLOWED BY ARTIFICIAL FILTRATION AND FILTRATION THROUGH LAND.

BARNOLDSWICK URBAN DISTRICT.—BARNOLDSWICK SEWAGE WORKS.

Date completed and brought into operation	March, 1897.		
Engineer	Messrs. Brierley & Holt, Blackburn.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	About 2,500 houses.		
Average daily flow of sewage in dry weather	About 45,000.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Wholly domestic. No.		
Number of water closets in area drained	30 W.C. 800 tippers.		
LAND.			
Total area	5 acres.		
Whether underdrained, and how?	Yes. Agricultural drain pipes.		
Nett area upon which sewage can be treated	4½ acres.		
TANKS.			
Number and total capacity	3. 35,620 gallons each = Total 106,860.		
Used all together, or in series	In series.		
Whether flow of sewage continuous, or time allowed for settlement	Settlement allowed.		
CHEMICALS.			
Nature	Ferozone (International Company's system).		
Quantity	From 8 to 10 grains per gallon.		
How added	By patent mixer.		
FILTERS.			
Number and total area	3. About 18 × 30 feet each.		
Construction	Rough gravel sand Polarite sand.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. No.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	3.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable valves.		
Proportion of flow in sewer to average flow when storm overflows begin to act	About double volume.		
COST OF—			
Land	I have no figures.		
Laying out of land	Do.		
Tanks	Do.		
Filters	Do.		
	1895.	1896.	1897.

Appendix 4.

FEATHERSTONE URBAN DISTRICT.—SOUTH FEATHERSTONE SEWAGE WORKS.

Date completed and brought into operation	
Engineer	Mr. Geo. Hodson, M.I.C.E., Westminster.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Present time 1,395 houses. Area about 1,400 acres.
Average daily flow of sewage in dry weather	75,000 gallons per 24 hours.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, with a little trade.
Number of water closets in area drained	About 30.
LAND.	
Total area	29 acres.
Whether underdrained, and how?	Yes. At 6 feet deep, 5 yards apart, 3-inch tiles.
Nett area upon which sewage can be treated	About 12 acres.
TANKS.	
Number and total capacity	2 tanks, 100 × 50 × 2 feet 3 inches. 3 tanks, 60 × 30 × 3 feet, one of which now converted into Dibdin filter.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	
How added	In blocks in sewage flow.
FILTERS	
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Three on sewers, 1 at outfall.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	2 act when sewer $\frac{2}{3}$ full, one when sewer is gorged and under pressure.
COST OF—	
Land	Have not these particulars.
Laying out of land	Do.
Tanks	Do.
Filters	Do.

	1895.	1896.	1897.
SLUDGE.			
Amount	No particulars kept.	Sludge dug into land as made.	
How dealt with	Do.		
Cost, or	Do.		
Return	Do.		
PRODUCE.			
Crops	Mangle Wurtzel.	Turnip, Swede.	Rye Grass, Oats.
Value	Crops are worth about £100 per annum.		
WORKING EXPENSES.			
Labour	Cannot allocate these particulars.		
Chemicals	Do.		
Pumping	Do.

Appendix.

FEATHERSTONE URBAN DISTRICT.—SNYDALE SEWAGE WORKS.

Date completed and brought into operation	October, 1898.
Engineer	Messrs. G. & F. W. Hodson, Westminster. W. A. Palliser, [Resident Engineer for the works.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 2,500 acres. Population, estimated, 4,000.
Average daily flow of sewage in dry weather	Not gauged, but about 70,000 gallons for 24 hours.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes, to some extent.
Number of water closets in area drained	About 20.
LAND.	
Total area	7 acres.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	6 acres.
TANKS.	
Number and total capacity	One inverted cone tank. 60,000 gallons.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Not yet decided.
How added	In blocks in sewage flow.
FILTERS.	
Number and total area	Seven. One of about 200 square yards, 6 of total area 300 square yards.
Construction	9 inches clinker, 26 inches coke, 6 inches coal or broken stone.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	One continuously for 6 days, 1 day's aëration; six intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two on sewer, one at outfall.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	When sewer running ¾ full.
COST OF—	
Land	Total cost £8,500.
Laying out of land	
Tanks	
Filters	

	1895.	1896.	1897.

Appendix 4.

NORMANTON URBAN DISTRICT.—NORMANTON SEWAGE WORKS.

Date completed and brought into operation	1887.
Engineer	Messrs. Brundell & Simmons, Doncaster.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,228 acres. 12,570 estimated population.
Average daily flow of sewage in dry weather	100,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	(1) Domestic. (2) Yes.
Number of water closets in area drained	49.
LAND.	
Total area	$4\frac{1}{2}$ acres.
Whether underdrained, and how?	4×6 inch field pipes, branches 12 feet apart.
Nett area upon which sewage can be treated	$2\frac{1}{2}$ acres.
TANKS.	
Number and total capacity	Three. 75,000 gallons.
Used all together, or in series	Used all together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	14 cwts. per week.
How added	In slabs as delivered.
FILTERS.	
Number and total area	Three.
Construction	12 inches of gravel, 12 inches of polarite and sand, and 15 inches of sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. No.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	Say normal flow $\frac{1}{6}$ when overflow acts $\frac{5}{6}$
COST OF—	
Land	£1,083 11*s.* 0*d.*
Laying out of land	£338 8*s.* 0*d.*
Tanks	£345 18*s.* 2*d.*
Filters	£317 1*s.* 8*d.* Engine house and machinery £528 11*s.* 11*d.*

Appendix 4.

RAWMARSH URBAN DISTRICT.—RAWMARSH SEWAGE WORKS.

Date completed and brought into operation	17th December, 1896.
Engineer	Mr. J. Platts, Rotherham.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,581 acres. 2,668 houses. 13,340 population.
Average daily flow of sewage in dry weather	250,000.
Nature of sewage (domestic or mixed with trade refuse.) Is surface water included?	Both. Partly.
Number of water closets in area drained	327.
LAND.	
Total area	Eleven acres.
Whether underdrained, and how?	3-inch agricultural pipes, 25 feet 0 inch apart, average depth 1 foot 10 inches, and conducted into 9-inch main carrier and open dyke to the River Don.
Nett area upon which sewage can be treated	8 acres.
TANKS.	
Number and total capacity	3 nests of 100,776 gallons each.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Not continuous. 4 to 8 hours allowed for settlement.
CHEMICALS.	
Nature	Ferozone.
Quantity	16 grains per gallon.
How added	By Kierby's mixing apparatus.
FILTERS.	
Number and total area	4=1,170 square feet.
Construction	Polarite.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method?	Intermittently. No.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	4; none at outfall works.
Construction — whether fixed side weirs, leaping weirs, or adjustible valves	2 adjustable valves. 2 fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	The adjustable valves are never opened, and one side weir is fixed too high to act, and one at the pumping station does not come into operation until all the storage tanks are overflowing. Capacity 140,000 gallons.
COST OF—	
Land	£1,942 13*s*. 0*d*.
Laying out of land Tanks Filters	£6,865. We are unable to ascertain the cost of each separate, as the contract has not been certified for by the Engineer.

	1895.	1896.	1897.
SLUDGE.			
Amount			589 tons per ann., containing 50 per cent. moisture, or about 300 tons dry.
How dealt with			Given to farmers.
Cost, or			No special labour. Gas engine to pump. Gas account, £20 3*s*. 2*d*.
Return			Do.
PRODUCE.			
Crops			Rye grass sold for about £4, and 10 tons in stock.
Value			
WORKING EXPENSES.			
Labour			£248 2 4
Chemicals			£216 0 0
Pumping			£191 8*s*. 10d., which includes all expenses incurred (labour only £86 3*s*. 2*d*.)

Appendix 4.

THORNTON URBAN DISTRICT.—THORNTON SEWAGE WORKS.

Date completed and brought into operation	September 25th, 1895.		
Engineer	John Drake, A.M.I.C.E., Queensbury, near Bradford.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	141 acres. 800 houses. 4,000 population.		
Average daily flow of sewage in dry weather	120,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and surface water included.		
Number of water closets in area drained			
LAND.			
Total area	4 acres 29¾ perches.		
Whether underdrained, and how?	Underdrained. 4-inch land tiles.		
Nett area upon which sewage can be treated	About two acres.		
TANKS.			
Number and total capacity	Receiver 126,562 gallons, 6 precipitation tanks 225,000.		
Used all together, or in series	In series of three.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.		
CHEMICALS.			
Nature	Alumino-ferric.		
Quantity			
How added	In slabs washed in open channel.		
FILTERS.			
Number and total area	Two, each 60 feet × 20 feet = 133 yards each.		
Construction	Sand only.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Three.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Overleaping.		
Proportion of flow in sewer to average flow when storm overflows begin to act	4 volumes.		
COST OF—			
Land	£496 11*s.* 4*d.*		
Laying out of land, Tanks, Filters	£3,563·12*s.* 0*d.*

Appendix 4.

DONCASTER RURAL DISTRICT.—CONISBROUGH SEWAGE WORKS.

Date completed and brought into operation	
Engineer	George White.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1856. Population 9,280.
Average daily flow of sewage in dry weather	855,000.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic.
Number of water closets in area drained	About 20.
LAND.	
Total area	3 acres.
Whether underdrained, and how?	Underdrained. 4 inch pipes.
Nett area upon which sewage can be treated	$2\frac{1}{2}$ acres.
TANKS.	
Number and total capacity	Three. 66 feet × 27 feet × 6 feet, capacity 57,888 each.
Used all together, or in series	Alternative.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	International purification by means of the addition of polarite and ferozone.
Quantity	
How added	
FILTERS.	
Number and total area	Six. 2,364 square feet.
Construction	Broken stone, gravel, and polarite.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One near ferry and one near outfall site.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable.
Proportion of flow in sewer to average flow when storm overflows begin to act	One and $\frac{1}{2}$.

HEMSWORTH RURAL DISTRICT.—SHAFTON TWO GATES SEWAGE WORKS.

Date completed and brought into operation	1892.
Engineer	T. H. Richardson.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only.
Number of water closets in area drained	None.
LAND.	
Total area	½ acre.
Whether underdrained, and how?	Not underdrained.
Nett area upon which sewage can be treated	⅛ acre.
TANKS.	
Number and total capacity	Two tanks, 10 feet 0 inch × 10 feet 0 inch each 3 feet deep.
Used all together, or in series	Used in series.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	2 filters, 16 feet 0 inch × 16 feet 0 inch each 4 feet deep.
Construction	Sand and polarite.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Continuous flow.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—

HUNSLET RURAL DISTRICT.—HALTON (PORTION OF TEMPLE NEWSAM) SEWAGE WORKS

Date completed and brought into operation	January, 1898.		
Engineer	Sam Shaw, Dewsbury.		
Whether sanctioned by L.G.B.			
Area and population or number of houses drained	316 houses. Surface water into storm water sewers.		
Average daily flow of sewage in dry weather	About 12,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Part surface and part roof water of a small part.		
Number of water closets in area drained	Eighteen.		
LAND.			
Total area			
Whether underdrained, and how?			
Nett area upon which sewage can be treated			
TANKS.			
Number and total capacity	Two. 20,000 gallons.		
Used all together, or in series	Together or separately.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Alumino-ferric.		
Quantity	41 cwts. in six months.		
How added	Slabs on end or edge at point of discharge from sewer.		
FILTERS.			
Number and total area	Four. 1,740 feet super.		
Construction	Drain tiles on bottom, general mixture—gravel, coke breeze, and burnt shale.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. No.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	One at outfall.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Small weir adjustable.		
Proportion of flow in sewer to average flow when storm overflows begin to act	The whole could be let go.		
COST OF—			
Land			
Laying out of land			
Tanks	About £500		
Filters			
	1896.	**1897.**	**1898.**
SLUDGE.			
Amount			About 7 to 8 tons.
How dealt with	Run from tanks on to clinker bed faced with ashes to drain. When cartable to land.

Appendix 4.

ROTHERHAM RURAL DISTRICT.—CANKLOW (WHISTON) SEWAGE WORKS.

Date completed and brought into operation	1897.
Engineer	J. Platts.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	221 houses. Estimated population, 1,200.
Average daily flow of sewage in dry weather	24,360 gallons, estimated.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. No trade sewage. A little yard water. Roof water caught in tubs.
Number of water closets in area drained	Three.
LAND.	
Total area	2 acres.
Whether underdrained, and how?	Yes. Every 10 feet.
Nett area upon which sewage can be treated	1½ acres.
TANKS.	
Number and total capacity	Nest of 5 on Magnetite's system. 1,700 gallons each.
Used all together, or in series	Used continuously.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Magnetite's Co.'s ferral.
Quantity	6 cwt. per 1,000,000 gallons.
How added	Placed under pump outlet in bulk and mixed in mixing race.
FILTERS.	
Number and total area	2. 200 square feet each.
Construction	Brick walls, filtering, and magnetite sand medium.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Alternate 24 hours. Not Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£400.
Laying out of land	£422
Tanks	£300
Filters	£300.

	1895.	1896.	1897.
SLUDGE.			
Amount			1½ tons per week, fairly dry.
How dealt with			Spread out on adjoining fields.
Cost, or			Nil.
Return			
PRODUCE.			
Crops			Not yet planted.
Value			
WORKING EXPENSES.			
Labour			10s. per week.
Chemicals			£26 per annum.
Pumping			£25 per annum, say £5 for oil, waste, and renewal.

Appendix 4.

SADDLEWORTH RURAL DISTRICT—DELPH, DIGGLE, AND DOBCROSS SEWAGE WORKS.

Date completed and brought into operation	31st December, 1896.
Engineer	Mr. T. S. McCallum, Manchester.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 4,160.
Average daily flow of sewage in dry weather	41,600 gallons (estimated).
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. A portion of surface water conveyed to works.
Number of water closets in area drained	
LAND.	
Total area	$4\frac{1}{2}$ acres.
Whether underdrained, and how?	Partially.
Nett area upon which sewage can be treated	$1\frac{1}{4}$ acres.
TANKS.	
Number and total capacity	2 tanks, each 17 feet 6 inches diameter × 12 feet 0 inches deep. 36,079 gals.
Used all together, or in series	Sometimes together, sometimes singly, according to flow.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 9 cwt. per week.
How added	Basket in inlet channel.
FILTERS.	
Number and total area	3 beds, each 28 feet 9 inches × 15 feet 0 inches; 144 square yards.
Construction	About 2 feet 5 inches filtering material in centre, made up as follows:—Sand 7 inches, polarite 6 inches, mixed with 4 inches sand, pea gravel 2 inches, bean gravel 3 inches, walnut gravel 2 inches, boulders 5 inches.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	7 on sewers, 1 at works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weirs on sewers, automatic arrangements at works.
Proportion of flow in sewer to average flow when storm overflows begin to act	7 to 10 times.
COST OF.	
Land	£1,103.
Laying out of land	Not yet completed.
Tanks	
Filters	

	1895.	1896.	1897.

Appendix 4

SWINTON URBAN DISTRICT.—SWINTON SEWAGE WORKS. (Alterations and Additions).

Date completed and brought into operation	20th December, 1898.
Engineer	R. Fowler, C.E.
Whether sanctioned by L.G.B.	Yes. Amount £2,000.
Area and population or number of houses drained	2,284 houses.
Average daily flow of sewage in dry weather	About 150,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included ?	Little trade refuse. Part.
Number of water closets in area drained	116.
LAND.	
Total area	6·647 acres.
Whether underdrained, and how ?	Yes.
Nett area upon which sewage can be treated	5 acres.
TANKS.	
Number and total capacity	Two. 42,587 gallons each = 85,174.
Used all together, or in series	Together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	8 to 10 grains per gallon.
How added	Slabs of alumino-ferric placed in channel dissolving in the sewage in proportion to the depth of immersion.
FILTERS.	
Number and total area	4 = 600 square yards.
Construction	Coke breeze.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Five.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	When the rainfall increases the volume to be pumped exceeding the rate of 600 gallons per minute, all above that quantity discharges untreated.
COST OF—	
Land	£2,150.
Laying out of land	No record.
Tanks	£1,341 15*s.* 4*d.*
Filters	(included above)

Appendix 4.

TONG URBAN DISTRICT.—DUDLEY HILL SEWAGE WORKS.

Date completed and brought into operation	Used first time November 21st, 1898, but not completed.
Engineer	John Drake, A.M.I.C.E., Queensbury.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	227 acres drained. 1,200 houses at 5 = 6,000.
Average daily flow of sewage in dry weather	Estimated 180,000 at 30 gallons per head.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed sewage. Yes.
Number of water closets in area drained	
LAND.	
Total area	4 acres 2 roods 12 perches enclosed for filtration areas.
Whether underdrained, and how?	Yes, by 4-inch land tiles, 11 yards apart in lines.
Nett area upon which sewage can be treated	14,085 superficial yards = 2 acres 3 roods 26 perches.
TANKS.	
Number and total capacity	Receiving dams, 126,562 gallons. 6 precipitating tanks 225,000 gallons.
Used all together, or in series	In series of 3.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 3 cwts. per day.
How added	In slab in open channel.
FILTERS.	
Number and total area	No. 2, each 360 yards superficial.
Construction	Sand and polarite.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Will be used continuously and alternately.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed leaping weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	7 Volumes.
COST OF—	
Land	Not yet paid for. Amount of loan sanctioned, £5,900. Amount of tender accepted £5,850. The works not measured off and certified.
Laying out of land	
Tanks	
Filters

Appendix 4.

WAKEFIELD RURAL DISTRICT.—CRIGGLESTONE SEWAGE WORKS.

Date completed and brought into operation	Early in 1897.
Engineer	Frank Massie, Assoc. M.Inst. C.E., Wakefield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	520 acres. 810 population at present.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water excluded as far as possible.
Number of water closets in area drained	Not more than 6.
LAND.	
Total area	4 acres 3 roods 5 perches.
Whether underdrained, and how?	Yes, but only one intercepting subsoil drain.
Nett area upon which sewage can be treated	1¼ acres.
TANKS.	
Number and total capacity	One Candy upward flow tank 14 feet 6 inches in diameter.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	4 tons a year.
How added	Blocks placed in inlet channel.
FILTERS.	
Number and total area	Two. 54 square yards.
Construction	Polarite, gravel, and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently, but not on Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	No record.
COST OF—	
Land	Taken on lease at £5 per acre.
Laying out of land	No exact record.
Tanks	Do.
Filters	Do.

Appendix 4.

WETHERBY UNION DISTRICT.—THORPARCH INDUSTRIAL SCHOOL SEWAGE WORKS.

Date completed and brought into operation	Midsummer, 1898.
Engineer	
Whether sanctioned by L.G.B.	
Area and population or number of houses drained	School for 100 girls and 12 servants and officers.
Average daily flow of sewage in dry weather	1,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. One or two overflows from soft-water cisterns.
Number of water closets in area drained	4. Laundry gives the most sewage.
LAND.	
Total area	14 acres.
Whether underdrained, and how?	The land drains communicate with the road ditches.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	One deep tank (covered), which was originally constructed for sump. This tank we used as a "septic tank," except we have a ventilating shaft 36 feet high.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	No.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	2, each 16 feet by 9 feet.
Construction	Brick and cement, broken stone at bottom and coarse coke breeze, with fine topping.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Used alternately, changed daily. Practically Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None, practically.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	
Laying out of land	
Tanks	Was built 30 years ago. No knowledge of its cost.
Filters	2. Were constructed at a cost of about £250, which included the cutting of trenches and laying drains.

	1895.	1896.	1897.

ARTIFICIAL FILTRATION.

GREASBORO' URBAN DISTRICT.—MANGHAM ROAD SEWAGE WORKS.

Date completed and brought into operation	1886 (Information not supplied by Authority.)
Engineer	Brundell & Simmons.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes.
Number of water closets in area drained	
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	1 septic and 1 detritus.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	3 filters.
Construction	Coke breeze.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act

Appendix 4.

HORSFORTH URBAN DISTRICT.—HORSFORTH SEWAGE WORKS.

Date completed and brought into operation	28th July 1898.
Engineer	William Spinks, Esq., A.M.I.C.E., Leeds.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	No. of houses drained about 1,720.
Average daily flow of sewage in dry weather	113,000 gallons (estimated at).
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Chiefly domestic. Surface water is included to some extent. It is kept out where possible.
Number of water closets in area drained	About 92.
LAND.	
Total area	About 6¼ acres.
Whether underdrained, and how?	Nothing is done to it as yet.
Nett area upon which sewage can be treated	About 4½ acres, exclusive of filters.
TANKS.	
Number and total capacity	There are no tanks.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	No chemicals are used.
Quantity	
How added	
FILTERS.	
Number and total area	Eight filters. Total area about 256 square yard.
Construction	Excavated in clay.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently on Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None, except at outfall. The present filters treat about 20,000 gallons per day, the rest of the sewage flowing into Cow Beck. Plans are being prepared by Mr. Spinks to treat the whole of the sewage on Dibdin's method. There is, at present, no properly constructed storm overflow.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£1,595.
Laying out of land	
Tanks	
Filters	£297 was the amount of contract.

SOUTHOWRAM URBAN DISTRICT.—HAIGH FIELD (SOUTHOWRAM) SEWAGE WORKS.

Date completed and brought into operation	October, 1895.
Engineer	W. H. D. Horsfall.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	No. of houses drained 75. Average population 5 per house, 375
Average daily flow of sewage in dry weather	Varies a good deal.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic (only). No surface water.
Number of water closets in area drained	None.
LAND.	
Total area	Four acres.
Whether underdrained, and how?	The land has all been quarried and filled in.
Nett area upon which sewage can be treated	Three acres.
TANKS.	
Number and total capacity	No., 3 tanks. 14 feet x 10 feet x 3 feet 6 inches, total capacity 10,695 gallons.
Used all together, or in series	Used all together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Two tanks answer as filters
Construction	Stone walls and concrete.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Used continuously.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	None.
Proportion of flow in sewer to average flow when storm overflows begin to act	None.
COST OF—	
Land	£8 a year. 30 years' lease from 2nd February, 1893.
Laying out of land	
Tanks	About £150.
Filters	

	1895.	1896.	1897.

HUNSLET RURAL DISTRICT.—MIDDLETON SEWAGE WORKS.

Date completed and brought into operation	November, 1898.
Engineer	Sam Shaw, C.E., Dewsbury.
Whether sanctioned by L.G.B.	No. Money not borrowed.
Area and population or number of houses drained	72 houses at present.
Average daily flow of sewage in dry weather	About 6,000 gallons in 24 hours.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage. Surface water not included, except from roofs, yards, &c.
Number of water closets in area drained	
LAND.	
Total area	No land is used, but plenty might be had, if required.
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.
CHEMICALS.	
Nature	Do.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Six. Total average area=472 square yards.
Construction	3 "coarse, composed of broken bricks, and 3 "fine, composed of coke breeze (pea size).
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently on Dibdin's system.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	20 times the dry weather flow at least.
COST OF—	
Land	Leased at £25 per annum.
Laying out of land	
Tanks	
Filters	Filters alone cost £240. Outfall works altogether cost £460.

TADCASTER RURAL DISTRICT.—HOLLINGHURST VILLAGE, ALLERTON BYWATER, SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	About 3 years ago.
Engineer	Mr. James Blackburn, C.E.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	About 50 houses. Population 250.
Average daily flow of sewage in dry weather	About 1,250 gallons daily.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. None.
Number of water closets in area drained	None.
LAND.	
Total area	About one rood.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	Only through filter beds.
TANKS.	
Number and total capacity	
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	None.
Quantity	
How added	
FILTERS.	
Number and total area	Two filters. 18 feet square by 3 feet deep each.
Construction	Built of brick. Charged with chequers, coke breeze and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not on Dibdin's method—on Mr. Denham's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One inlet sewer only.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	None.
Proportion of flow in sewer to average flow when storm overflows begin to act	Little or no difference, as there is no surface water connected to sewers.
COST OF—	
Land	Messrs. T. & R. W. Bowers are the lessors of the land
Laying out of land	No.
Tanks	No.
Filters	About £200 in laying main sewer and building filter beds.

	1895.	1896.	1897.
SLUDGE.			
Amount		About 2 tons.	About same as 1896.
How dealt with		Spread on land.	
Cost, or		About £2.	
Return		Nil.	
PRODUCE.			
Crops		No accounts are kept.	
Value			
WORKING EXPENSES.			
Labour		5s. a week.	
Chemicals		Coke breeze £5.	
Pumping

Appendix 4.

TADCASTER RURAL DISTRICT.—GARFORTH SEWAGE WORKS.

Date completed and brought into operation	About 27 years ago.
Engineer	Messrs. Towlers, of Leeds.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 452 houses. Population about 2,260.
Average daily flow of sewage in dry weather	About 11,000 gallons daily.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. Surface water partly included.
Number of water closets in area drained	About 30.
LAND.	
Total area	One acre.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	About ½ acre.
TANKS.	
Number and total capacity	*Six were first made, are now filters.
Used all together, or in series	Two at a time.
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 5 tons a year.
How added	One cake always standing in stream of sewage.
FILTERS.	
Number and total area	*Six. About 30 yards long, 2 yards wide, 5 feet deep.
Construction	Peat moss and coke breeze.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not on Dibdin's method—Mr. Wm. Green's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One inlet and 2 outlets, top and bottom of beds.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	No. One wooden sluice.
Proportion of flow in sewer to average flow when storm overflows begin to act	When wet there will be 20 gallons of storm water for one gallon of sewage.
COST OF—	
Land	£2,700.
Laying out of land	
Tanks	
Filters	£50 spent in present filters when made.

	1895.	1896.	1897.
SLUDGE.			
Amount		60 tons.	60 tons.
How dealt with		Sold.	Sold.
Cost, or		Peat moss £18 3 6	£18 3 6

Appendix 4

TADCASTER RURAL DISTRICT.—NEW MICKLEFIELD SEWAGE WORKS.

Date completed and brought into operation	About 7 years ago. No date kept.
Engineer	Mr. Charles Houfton, C.E.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	About 171 houses, with a population of 855.
Average daily flow of sewage in dry weather	About 8,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. No.
Number of water closets in area drained	None.
LAND.	
Total area	About one rood.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	Only through the filters.
TANKS.	
Number and total capacity	No.
Used all together, or in series	No.
Whether flow of sewage continuous, or time allowed for settlement	No.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	One cake always standing in sewage stream.
How added	Cake added whenever required.
FILTERS.	
Number and total area	Four. 18 feet square, 3 feet deep, each.
Construction	Built of brick. Charged with chequers, coke breeze, and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	One bed used every fourth week, or when required. Not on Dibdin's method—on Mr. Denham's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One line of sewers only.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	None.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—	
Land	The Micklefield Coal Co. Ld. are lessors of land.
Laying out of land	
Tanks	
Filters	Four filters cost about £120, or £30 each.

	1895.	1896.	1897.
SLUDGE.			
Amount			About 12 tons.
How dealt with			Carted on land
Cost, or			No accounts kept.
Return			Do.
PRODUCE.			
Crops			Do.
Value			Do
WORKING EXPENSES.			
Labour			18s. per week for man.
Chemicals			£11 a year and making beds.
Pumping			£20 once a year.

Appendix 4.

TADCASTER RURAL DISTRICT.—NEWTHORPE SEWAGE WORKS.

Date completed and brought into operation	August, 1893.
Engineer	Mr. Robinson, the owner.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	About 100 inhabitants, or 21 houses.
Average daily flow of sewage in dry weather	About 300 gallons daily.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic only. No.
Number of water closets in area drained	None.
LAND.	
Total area	About 20 square yards.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	Nil.
TANKS.	
Number and total capacity	
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	None.
Quantity	
How added	
FILTERS.	
Number and total area	Two filters, about 9 feet square each 3 feet deep.
Construction	Chequers, coke breeze, and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not Dibdin's method—Mr. Denham's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	No.
Proportion of flow in sewer to average flow when storm overflows begin to act	No.
COST OF—	
Land	Nil. Filters built on owner's land.
Laying out of land	Nil.
Tanks	Nil.
Filters	About £42 for building filters and laying sewer.

	1895.	1896.	1897.
SLUDGE.			
Amount			About $\frac{1}{2}$ ton for 1 year.
How dealt with			Deposited in gardens.
Cost, or			No account kept.
Return			Do.
PRODUCE.			
Crops			Garden produce.
Value			No account kept.
WORKING EXPENSES.			
Labour			About £2 a year.
Chemicals			Coke and sand £2 a year.
Pumping

FILTRATION THROUGH LAND.

BALBY-WITH-HEXTHORPE URBAN DISTRICT. BALBY SEWAGE WORKS.

Date completed and brought into operation	About 1882.
Engineer	The late B. S. Brundell.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 400 acres. Population 2,300.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic.
Number of water closets in area drained	
LAND.	
Total area	11 acres.
Whether underdrained, and how?	Underdrained.
Nett area upon which sewage can be treated	10 acres.
TANKS.	
Number and total capacity	One.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Used to receive sewage from the low level section and pumped out.
CHEMICALS.	
Nature	None used.

Appendix 4.

BARNSLEY URBAN DISTRICT.—BARNSLEY SEWAGE WORKS.

Date completed and brought into operation	July 17th, 1877.
Engineer	John Bailey Denton, C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 2,000 acres and 8,000 houses.
Average daily flow of sewage in dry weather	1,250,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, mixed with trade refuse from dye, bleach, and printing works and breweries. Some surface water is admitted.
Number of water closets in area drained	About 2,000.
LAND.	
Total area	96 acres.
Whether underdrained, and how?	Yes, at a depth of from 4 to 6 feet.
Nett area upon which sewage can be treated	55 acres.
TANKS.	
Number and total capacity	2. Only screening and road detritus.
Used all together, or in series	Together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Lime and alumino-ferric. Since July, 1898.
Quantity	About five grains each per gallon.
How added	Milk of lime and alumino-ferric slabs.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	This is uncertain.
COST OF—	
Land	£23,955 15s. 0d.
Laying out of land	£6,022 7s. 9d.
Tanks	Included in the above.
Filters	None.

	1895.	1896.	1897.

Appendix 4.

CLECKHEATON URBAN DISTRICT.—SCHOLES SEWAGE WORKS.

Date completed and brought into operation	1890.
Engineer	Messrs. Woodhead.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,700. 420 houses.
Average daily flow of sewage in dry weather	30,474 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Partly, but a scheme has just been sanctioned to take out the greater portion.
Number of water closets in area drained	6.
LAND.	
Total area	10 acres.
Whether underdrained, and how?	No, but scheme under consideration.
Nett area upon which sewage can be treated	9 acres.
TANKS.	
Number and total capacity	Nil.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Nil.

DONCASTER BOROUGH URBAN DISTRICT.—SANDALL SEWAGE WORKS.

Date completed and brought into operation	1873.
Engineer	The late B. S. Brundell, C.E., in consultation with the late Sir Robert Rawlinson, C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Portions of Doncaster and suburbs of Balby-with-Hexthorpe and Wheatley. Estimated sewage population 32,000.
Average daily flow of sewage in dry weather	640,000 gallons per day.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Chiefly domestic, breweries, and tanneries. Surface water included, except Hexthorpe and Wheatley.
Number of water closets in area drained	About 3,800.
LAND.	
Total area	288 acres.
Whether underdrained, and how?	About 30 acres undrained. This is being extended.
Nett area upon which sewage can be treated	237 acres. The balance near main roads being freed from sewage.
TANKS.	
Number and total capacity	One triangular tank not now used.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Do.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Three on line of sewers. One near outfall tank, but not used.
Construction—whether fixed side weirs, leaping weirs, or adjustible valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	About 5 to 1 gauged by capacity of one engine. About 10 to 1 gauged by capacity of both engines.
COST OF—	
Land	Not known. The land belonged to the Corporation.

Appendix 4.

HARROGATE BOROUGH URBAN DISTRICT. HARROGATE SEWAGE WORKS.

Date completed and brought into operation.	1878.		
Engineer	E. Wareham Harry, C.E. (the then surveyor).		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	Area 1,287 acres. Population about 20,000.		
Average daily flow of sewage in dry weather	About 800,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. Surface water is partially dealt with by separate drains, and further surface water drains are being constructed.		
Number of water closets in area drained	5,295.		
LAND.			
Total area	321 acres.		
Whether underdrained, and how?	Partially. Agricultural drain pipes.		
Nett area upon which sewage can be treated	293 acres.		
TANKS.			
Number and total capacity.	None.		
Used all together, or in series	Do.		
Whether flow of sewage continuous, or time allowed for settlement	Do.		
CHEMICALS.			
Nature	Do.		
Quantity	Do.		
How added	Do.		
FILTERS.			
Number and total area	Two bacteriological ones, each 5 yards × 4 yards. Experimental only.		
Construction	Brickwork and concrete.		
Whether used continuously or intermittently and (if the latter) whether on Dibdin's method	Intermittently. Dibdin's method.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Twelve.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves.	1 adjustable leaping weir. 9 fixed side weirs. 2 with pipe outlet in wall of manhole above top of sewer.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Varies considerably. Sewage 3 or 4 times diluted. In no case does storm overflow come into operation until sewer is two-thirds full.		
COST OF—			
Land	About £18,000.		
Laying out of land			
Tanks			
Filters			
	1895.	1896.	1897.
SLUDGE.			
Amount			
How dealt with	No sludge. Crude sewage run on to land.		
Cost, or	Man attending to sewage. £62 8s. 0d. per annum.		
Return			
PRODUCE.			
Crops	Roots, corn, rye grass, etc.		
Value	£6,456.	£4,987.	£6,112. Farm receipts.
WORKING EXPENSES.			
Labour	£5,035.	£6,107.	£5,843. Farm expenditure.

IDLE URBAN DISTRICT.—IDLE SEWAGE WORKS.

Date completed and brought into operation	About November, 1894.
Engineer	Messrs. W. B. Woodhead & Sons.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	760 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Only where not possible to get into old drains.
Number of water closets in area drained	50.
LAND.	
Total area	22 acres.
Whether underdrained, and how?	Underdrained.
Nett area upon which sewage can be treated	8 acres and 23 perches.
TANKS.	
Number and total capacity	Nil.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.
CHEMICALS.	
Nature	Do.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Beds.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittent downward filtration.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	1 leaping weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	The full amount including land, works, professional charges, and other expenses was £25,000.

Appendix 4.

KEIGHLEY BOROUGH URBAN DISTRICT.—KEIGHLEY SEWAGE WORKS.

Date completed and brought into operation	11th December 1894.
Engineer	W. H. Hopkinson, A.M.I.C.E., Borough Engineer.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	25,000 population.
Average daily flow of sewage in dry weather	780,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and trade mixed. Surface water included. Manufacturers treat before turning into sewer.
Number of water closets in area drained	
LAND.	
Total area	49½ acres under treatment, 80½ acres of additional land is used as ordinary farm.
Whether underdrained, and how?	Yes, by 6 inch pipes, 66 feet apart and 5 feet deep.
Nett area upon which sewage can be treated	40 acres.
TANKS.	
Number and total capacity	Two. 640 cubic feet. These are to intercept large solids.
Used all together, or in series	Used alternately.
Whether flow of sewage continuous, or time allowed for settlement	A few days are allowed for liquid to drain off before sludge is removed.
CHEMICALS.	
Nature	None used.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	One of 240 yards at level of coke.
Construction	Dug out of solid ground, filled with 20 inches of coke of various sizes.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	It is used only for the night flow of sewage between 10 p.m. and 6 a.m., when the composition is chiefly subsoil water.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None at works or on outfall sewer.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	One fixed side weir. 4 leaping weirs on intercepting sewer and various small ones.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£125 per acre.
Laying out of land	£12,500. Farm buildings £2,500.

MIRFIELD URBAN DISTRICT.—MIRFIELD SEWAGE WORKS.

Date completed and brought into operation	Partly in operation, not yet completed.
Engineer	Frederick Herbert Hare.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	2,000 houses drained.
Average daily flow of sewage in dry weather	150,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic only. No.
Number of water closets in area drained	200.
LAND.	
Total area	32 acres.
Whether underdrained, and how?	11 acres underdrained.
Nett area upon which sewage can be treated	25 acres at present, other leased out.
TANKS.	
Number and total capacity	Plans for tank arrangement and further underdrainage works have been sent to Local Government Board, and a public inquiry held.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	
Quantity	
How added	
FILTERS.	
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at Ledgard Bridge that cannot be used, also one at pumping station in case of breakdown.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Leaping weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	One-third of sewage gravitates to farm and is not affected by storm overflows. Other is retained in tank sewer and cannot rise to overflow unless pumps are standing 2 days.
COST OF—	
Land	£4,000.
Laying out of land	£700.

Appendix 4.

RIPON CITY URBAN DISTRICT.—RIPON SEWAGE WORKS.

Date completed and brought into operation	20th October 1896.
Engineer	Messrs. Preston & Johnson, 14, The Exchange, Bradford.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 1,000 acres. 1,800 houses.
Average daily flow of sewage in dry weather	300,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included ?	Mixed with trade effluent. A large proportion.
Number of water closets in area drained	587.
LAND.	
Total area	30 acres purchased, but only 12 acres laid out.
Whether underdrained, and how ?	9 inch pipes laid under the paths 6 feet below beds
Nett area upon which sewage can be treated	$8\frac{1}{2}$ acres.
TANKS.	
Number and total capacity	One straining tank only (8,000 gallons).
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None used.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	The land is laid out in level plots ($\frac{3}{4}$ acre each).
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Used intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Six on line of sewers, none at outfall.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	All fixed weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	At least 10 times.
COST OF—	
Land	About £150 per acre.
Laying out of land	About £2,450 for the above-mentioned 12 acres.
Tanks	
Filters	

	1895.	1896.	1897.

ROYSTONE URBAN DISTRICT.—CROSS LANE SEWAGE WORKS.

Date completed and brought into operation	1895.
Engineer	Joseph Latham, Barnsley.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	30 houses.
Average daily flow of sewage in dry weather	About 1,200 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic only. Surface water slight.
Number of water closets in area drained	None.
LAND.	
Total area	About 2 acres.
Whether underdrained, and how?	Underdrained with tiles.
Nett area upon which sewage can be treated	1½ acres.
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.

Appendix 4.

SKIPTON URBAN DISTRICT.—SKIPTON SEWAGE WORKS.

Date completed and brought into operation	1876.		
Engineer	Baldwin Latham, M.I.C.E.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	4,245 acres. About 12,000 population. About 2,300 houses.		
Average daily flow of sewage in dry weather	Not known and cannot well be ascertained.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and trade, with surface water included.		
Number of water closets in area drained	Nearly all houses have water closets.		
LAND.			
Total area	About 53 acres.		
Whether underdrained, and how?	Part 4 feet 6 × 4 feet tiles.		
Nett area upon which sewage can be treated	50 acres.		
TANKS.			
Number and total capacity	Two small tanks.		
Used all together, or in series	Worked together.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	None.		
Quantity	Do.		
How added	Do.		
FILTERS.			
Number and total area	No filters, but a grating through which sewage passes continuously.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	There is only one storm overflow on the farm. It has no valve, but a board is fixed to adjust the flow.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.

Appendix 4.

WOMBWELL URBAN DISTRICT.—WOMBWELL SEWAGE WORKS.

Date completed and brought into operation	January, 1886, for the first contract.
Engineer	The Board's Surveyor, Jno. Robinson.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	In the first instance only such part of Wombwell village as emptied into the canal.
Average daily flow of sewage in dry weather	Cannot say.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. No.
Number of water closets in area drained	None when works were completed. Waste water closets now beginning to be used.
LAND.	
Total area	16 acres.
Whether underdrained, and how?	Yes, by 6 inch sanitary tubes (about 16 feet apart) to main carriers.
Nett area upon which sewage can be treated	13 acres.
TANKS.	
Number and total capacity	No tanks in original scheme. Increase of population caused additional land, also tanks, necessary. Works now going on.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	No tanks yet completed. When completed time will be allowed for settlement.
CHEMICALS.	
Nature	Filters not yet ready.
Quantity	
How added	
FILTERS.	
Number and total area	There will be 16 tanks at the old farm, area 511 square yards, and 8 tanks at the Hemingfield farm, area 212 square yards.
Construction	Brick in cement and concrete.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Will be intermittent.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Three.

BOWLAND RURAL DISTRICT.—GISBURN SEWAGE WORKS.

Date completed and brought into operation	About the beginning of 1896.
Engineer	H. A. Johnson, C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Area 1,876 acres. Population of township 444. Living in district about 350. Houses drained 71.
Average daily flow of sewage in dry weather	About 3,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water not included.
Number of water closets in area drained	35.
LAND.	
Total area	4 acres.
Whether underdrained, and how?	Yes.
Nett area upon which sewage can be treated	4 acres.
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.
CHEMICALS.	
Nature	Sewage purified by broad irrigation.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Do
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Open carriers with grips.
Proportion of flow in sewer to average flow when storm overflows begin to act	No storm overflow.
COST OF—	
Land	Sewers and all complete, £2,103.
Laying out of land	
Tanks	
Filters	

	1895.	1896.	1897.
SLUDGE.	None.	In 1896 and 1897 the sewage land was let to a tenant, who managed and took the crops at £5 per year.

Appendix 4.

GREAT OUSEBURN RURAL DISTRICT.—ACOMB SEWAGE WORKS.

Date completed and brought into operation	1880.
Engineer	Charles Hornsey, York.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Area, 1,439 acres. Population, 2,181. Houses drained 480.
Average daily flow of sewage in dry weather	34,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage. No.
Number of water closets in area drained	90.
LAND.	
Total area	10 acres.
Whether underdrained, and how?	Underdrained every 11 yards.
Nett area upon which sewage can be treated	About 9 acres.
TANKS.	
Number and total capacity	Nil.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.

Appendix 4.

ROTHERHAM RURAL DISTRICT.—SWALLOW NEST SEWAGE WORKS.

Date completed and brought into operation	1880.
Engineer	D. Jennings.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Estimated population 1,000.
Average daily flow of sewage in dry weather	Not ascertained.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and surface water only.
Number of water closets in area drained	None.
LAND.	
Total area	$1\frac{3}{4}$ acres.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	$1\frac{1}{2}$ acres.
TANKS.	
Number and total capacity	2 cesspools, which cannot be called tanks.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	None.
Quantity	
How added	
FILTERS.	
Number and total area	None.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£5 per acre on a 21 years' lease.
Laying out of land	Not ascertainable.
Tanks	
Filters	

	1895.	1896.	1897.
SLUDGE.			
Amount	None.	None.	None.

Works admittedly unsatisfactory. New scheme in hand.

Appendix 4.

ROTHERHAM RURAL DISTRICT.—WHISTON SEWAGE WORKS.

Date completed and brought into operation	1877.
Engineer	D. Jennings.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,500 estimated population.
Average daily flow of sewage in dry weather	Cannot be ascertained on account of the enormous amount of water getting in out of the river bed.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and surface water included.
Number of water closets in area drained	None.
LAND.	
Total area	1 acre.
Whether underdrained, and how?	Every 20 feet.
Nett area upon which sewage can be treated	¾ of an acre.
TANKS.	
Number and total capacity	None.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	None.
Quantity	
How added	
FILTERS.	
Number and total area	None.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	Not ascertainable.
COST OF—	
Land	£10 per annum on a 21 years' lease.
Laying out of land	Not ascertainable.
Tanks	Nil.
Filters	Nil.

Appendix 4.

SEDBERGH RURAL DISTRICT.—DENT SEWAGE WORKS.

Date completed and brought into operation	November, 1898.
Engineer	R. Edgar Horsfall, Halifax.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 283. Houses drained 86.
Average daily flow of sewage in dry weather	1,250 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. No surface water is included.
Number of water closets in area drained	Three.
LAND.	
Total area	$3\frac{1}{3}$ acres.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	About 3 acres
TANKS.	
Number and total capacity	Nil.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.

SETTLE RURAL DISTRICT.—LONG PRESTON SEWAGE WORKS.

Date completed and brought into operation	November, 1898.
Engineer	Richard Armistead, Assoc.M.Inst.C.E., Bingley.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Approximate population 750.
Average daily flow of sewage in dry weather	22,800 gallons per day.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Partly.
Number of water closets in area drained	
LAND.	
Total area	5 acres.
Whether underdrained, and how?	Yes. 6 inch and 4 inch earthenware pipes.
Nett area upon which sewage can be treated	4 acres.
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.
CHEMICALS.	
Nature	Do.
Quantity	Do.
How added	Do.

TADCASTER RURAL DISTRICT.—SHERBURN SEWAGE WORKS.

Date completed and brought into operation	About 25 years ago.
Engineer	Mr. George Morley.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 251 houses. Population about 1,250.
Average daily flow of sewage in dry weather	About 3,765 gallons per day.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water from yards only.
Number of water closets in area drained	About 6 W.C.
LAND.	
Total area	7 acres of land.
Whether underdrained, and how?	Yes. Land tiles 3 inches.
Nett area upon which sewage can be treated	7 acres.
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Flowing on land daily, and filters through the soil.

WAKEFIELD RURAL DISTRICT.—SMALLEY BIGHT SEWAGE WORKS.

Date completed and brought into operation	Earley in 1896.
Engineer	Frank Massie, Assoc.M.Inst.C.E., Wakefield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,885 acres. 8,000 population (estimated.)
Average daily flow of sewage in dry weather	No record. Probably 160,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. No.
Number of water closets in area drained	Comparatively few. No exact record.
LAND.	
Total area	31 acres 3 roods 15 perches, of which 15 acres is sub-let to a farmer.
Whether underdrained, and how?	Only partially by trunk subsoil drains.
Nett area upon which sewage can be treated	12 acres are at present available, but this can be increased to 24 acres when necessary.
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.

WAKEFIELD RURAL DISTRICT.—SHITLINGTON SEWAGE WORKS.

Date completed and brought into operation	Early in 1897.
Engineer	Frank Massie, Assoc.M.Inst.C.E., Wakefield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	600 acres. 2,500 population.
Average daily flow of sewage in dry weather	No exact record. Probably 50,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water is excluded as far as possible.
Number of water closets in area drained	Very few.
LAND.	
Total area	6 acres 2 roods 5 perches.
Whether underdrained, and how?	Yes. By subsoil drains.
Nett area upon which sewage can be treated	5 acres 7 perches.
TANKS.	
Number and total capacity	None.

Appendix 4.

WETHERBY RURAL DISTRICT.—WETHERBY SEWAGE WORKS.

Date completed and brought into operation	
Engineer	A. E. Preston, Bradford.
Whether sanctioned by L.G.B.	
Area and population or number of houses drained	1,373 acres. 2,000 population. 468 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	
Number of water closets in area drained	About 35.
LAND.	
Total area	25½ acres.
Whether underdrained, and how?	Yes. Sanitary pipes.
Nett area upon which sewage can be treated	20 acres.
TANKS.	
Number and total capacity	None.
Used all together, or in series	Do.
Whether flow of sewage continuous, or time allowed for settlement	Do.
CHEMICALS.	
Nature	Do.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Do.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One on line of sewer.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	Rented, £65 per year.
Laying out of land	Not known.

CHEMICAL PRECIPITATION OR SETTLEMENT.

ARDSLEY URBAN DISTRICT.—WOMBWELL ROAD SEWAGE WORKS.

Date completed and brought into operation	12th June, 1895.
Engineer	Mr. T. S. McCallum, Manchester.
Whether sanctioned by L.G.B.	No (paid for out of current rates).
Area and population or number of houses drained	About 20 houses.
Average daily flow of sewage in dry weather	About 800 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes.
Number of water closets in area drained	
LAND.	
Total area	600 square yards.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	None, unless pumped.
TANKS.	
Number and total capacity	1 tank, 4 feet × 4 feet × 6 feet 3 inches deep. 625 gallons.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric at present.
Quantity	
How added	Basket in inlet channel.
FILTERS.	
Number and total area	No filter at present.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	
Laying out of land	
Tanks	About £20.

ECCLESHILL URBAN DISTRICT.—GREENGATES SEWAGE WORKS.

Date completed and brought into operation	1890. (Information not supplied by Authority.)
Engineer	
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	566 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade waste.
Number of water closets in area drained	
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	4 tanks. 85,351 gallons.
Used all together, or in series

EMLEY URBAN DISTRICT.—THORNCLIFFE LANE SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	In use about 3 years.
Engineer	Mr. Sam Shaw prepared the plans for the tanks.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	About 55 houses. Population 275.
Average daily flow of sewage in dry weather	Not calculated.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes.
Number of water closets in area drained	None.
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	(Precipitating). 2 tanks. Capacity not calculated.
Used all together, or in series	Together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alum.-ferric.
Quantity	As required.
How added	Tablet in Chambers.
FILTERS.	
Number and total area	Nil.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	Not calculated.

Appendix 4.

GOLCAR URBAN DISTRICT.—APPLEYARD SEWAGE WORKS.

Date completed and brought into operation	About 17 years ago.
Engineer	John Hanson & Co.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	917 houses drained.
Average daily flow of sewage in dry weather	Varies very much.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Surface water included.
Number of water closets in area drained	42.
LAND.	
Total area	No land treatment.
Whether underdrained, and how?	Do.
Nett area upon which sewage can be treated	Do.
TANKS.	
Number and total capacity	3 tanks. 30 feet × 24 feet, 3 feet 6 inches deep.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous
CHEMICALS.	
Nature	Alumino-ferric and lime.
Quantity	2 cwts. each per day.
How added	Automatic machine.
FILTERS.	
Number and total area	1 filter.
Construction	Natural.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Continuously.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	Cannot say.

GUISELEY URBAN DISTRICT.—GUISELEY SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	July, 1888.
Engineer	Preston & Johnson, Bradford.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 4,800. Area 1,554 acres.
Average daily flow of sewage in dry weather	270,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	All sewage, domestic and trade. No.
Number of water closets in area drained	
LAND.	
Total area	4 acres.
Whether underdrained, and how?	Yes. Land tiles laid 5 yards apart and 1 yard deep.
Nett area upon which sewage can be treated	1 acre.
TANKS.	
Number and total capacity	Eleven. 1 reception, 6 precipitation = 344,000 gallons; 1 aerating = 170,000 gallons; 3 mud tanks.
Used all together, or in series	All used together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Average, 2 tons per week.
How added	Slabs placed in channel and sewage dissolves it.
FILTERS.	
Number and total area	None. Plans are now in hand for providing filters to be worked on Dibdin's method.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	1 at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs, unmovable.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£1,500.
Laying out of land	£1,900.

HALIFAX COUNTY BOROUGH.—SALTERHEBBLE SEWAGE WORKS.

(Information not supplied by Authority.)

Date completed and brought into operation	1869.
Engineer	
Whether sanctioned by L.G.B.	
Area and population or number of houses drained	8,209 acres. Population (1891), 83,109.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Yes.
Number of water closets in area drained	
LAND.	
Total area	None.
Whether underdrained, and how?	Do.
Nett area upon which sewage can be treated	Do.
TANKS.	
Number and total capacity	11 tanks. 314,260 gallons.
Used all together, or in series	2 sets worked alternately.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	
How added	Put into channel.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Several on line of sewers. 2 at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Various kinds. Some fixed, some moveable.
Proportion of flow in sewer to average flow when storm overflows begin to act

HIPPERHOLME URBAN DISTRICT.—BAILIFFE BRIDGE WEST SEWAGE WORKS.

Date completed and brought into operation	Early in 1879.
Engineer	Richard Horsfall, Halifax.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 900 acres. Population about 2,675.
Average daily flow of sewage in dry weather	About 90,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Only one small tannery in addition to sewage. Yes.
Number of water closets in area drained	176 to houses with closets.
LAND.	
Total area	6,352 yards.
Whether underdrained, and how?	
Nett area upon which sewage can be treated	None.
TANKS.	
Number and total capacity	6. 36 feet × 14 feet, 30 inches deep.
Used all together, or in series	Series, 3 at a time.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	16 tons a year.
How added	Put in in slabs in mouth of drain.
FILTERS.	
Number and total area	None.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	About double quantity.
COST OF—	
Land	The entire cost of land and sewerage works was £9,000.

LEEDS COUNTY BOROUGH.—LEEDS SEWAGE WORKS

Appendix 4.

Date completed and brought into operation	Now being extended.
Engineer	City Engineer—Thos. Hewson.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	About eighty thousand houses.
Average daily flow of sewage in dry weather	Fifteen million gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Yes.
Number of water closets in area drained	From a population of about 250,000.
LAND.	
Total area	27 acres.
Whether underdrained, and how?	Occupied by tanks, sludge lagoons, buildings, &c.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	12 old tanks, $2\frac{1}{2}$ millions; 7 new tanks, 3 millions. Will be used all together, except that some of the 12 old ones will be used for experiments for some time to come.
Used all together, or in series	Will be used all together in series and with continuous flow.
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	Lime.
Quantity	Now using three grains per gallon.
How added	As milk of lime in pump well.
FILTERS.	
Number and total area	Experiments being made with biological beds.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at outfall works, great number in other places.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	All three ways.
Proportion of flow in sewer to average flow when storm overflows begin to act	Variable average, perhaps one-third.

ROTHERHAM RURAL DISTRICT.—CONCRETE, BRAMPTON BIERLOW, SEWAGE WORKS. Appendix 4.

Date completed and brought into operation	1896.
Engineer	B. Godfrey, A.M.Inst.C.E.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	106 houses.
Average daily flow of sewage in dry weather	8,000 gallons estimated.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, roof and yard water only.
Number of water closets in area drained	Nil.
LAND.	
Total area	1 acre. Effluent to colliery boilers.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	Nil.
TANKS.	
Number and total capacity	1 pair. 2,000 gallons each.
Used all together, or in series	Used together.
Whether flow of sewage continuous, or time allowed for settlement	Continuously.
CHEMICALS.	
Nature	Nil.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Do.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	1 on the line of sewer.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	44 times ordinary flow.
COST OF—	
Land	2*l.* per annum.
Laying out of land	Nil.
Tanks	90*l.*
Filters	Nil.

Appendix 4.

ROTHERHAM RURAL DISTRICT.—WENTWORTH SEWAGE WORKS.

Date completed and brought into operation	1895.		
Engineer	E. W. Ives.		
Whether sanctioned by L.G.B.	No.		
Area and population or number of houses drained	1,000 population estimated.		
Average daily flow of sewage in dry weather	15,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, and road water, surface water, and a good many field drains included.		
Number of water closets in area drained	Three.		
LAND.			
Total area	500 square yards.		
Whether underdrained, and how?	No.		
Nett area upon which sewage can be treated	None available.		
TANKS.			
Number and total capacity	1. Ives' patent, capacity unknown.		
Used all together, or in series			
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	14 cwt. alumino-ferric and alum cake answers fairly well to a million gallons. Others have been tried, but not so satisfactory.		
Quantity			
How added	Roughly broken in mixing race.		
FILTERS.			
Number and total area	None.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	1 at outfall works.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weir in line.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Twice ordinary flow.		
COST OF—			
Land	£2 per annum.		
Laying out of land	Nil.		
Tanks	£250.		
Filters	Nil.		
	1895.	**1896.**	**1897.**
SLUDGE.			
Amount	About 4 cubic yards per month.	Do.	Do.
How dealt with	Carted on to land.	Do.	Do.
Cost, or	10s. per month.	Do.	Do.
Return	Nil.

ROTHERHAM RURAL DISTRICT.—HARLEY SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	1895.
Engineer	E. W. Ives.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	500 estimated population.
Average daily flow of sewage in dry weather	6,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and road water only.
Number of water closets in area drained	None.
LAND.	
Total area	1,000 square yards.
Whether underdrained, and how?	Used to be, but has since been cut off.
Nett area upon which sewage can be treated	600 square yards.
TANKS.	
Number and total capacity	Ives' patent, capacity unknown.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric and alum cake, answers fairly well, others tried but not satisfactory.
Quantity	26 cwt. per million gallons, not allowing for rain water.
How added	Roughly broken in mixing race.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side of weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	Not known.
COST OF—	
Land	£2 per annum.
Laying out of land	Nil.
Tanks	£250.
Filters	Nil.

Appendix 4.

TODMORDEN RURAL DISTRICT.—HEPTONSTALL SEWAGE WORKS.

Date completed and brought into operation	1889.
Engineer	John Sutcliffe, Todmorden.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	212 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Only from roofs of houses.
Number of water closets in area drained	None.
LAND.	
Total area	About 2,200 square yards.
Whether underdrained, and how?	Yes, by agricultural pipes.
Nett area upon which sewage can be treated	About one-half.
TANKS.	
Number and total capacity	None.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric in slabs.
Quantity	About 20 lbs. per day.
How added	In manhole.
FILTERS.	
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	Leased, not purchased.
Laying out of land	
Tanks	
Filters

Appendix 4.

SETTLEMENT OR CHEMICAL PRECIPITATION, FOLLOWED BY FILTRATION THROUGH LAND.

ALTOFTS URBAN DISTRICT.—ALTOFTS SEWAGE WORKS.

Date completed and brought into operation	About February, 1880.		
Engineer	Mr. James Lumley, Bradford.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	1,690 acres. About 4,500.		
Average daily flow of sewage in dry weather	25,000 gallons per diem.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water partly included.		
Number of water closets in area drained	67		
LAND.			
Total area	4 acres 3 roods.		
Whether underdrained, and how?	Yes, with 6 inch earthenware pipes.		
Nett area upon which sewage can be treated	About $3\frac{1}{2}$ acres.		
TANKS.			
Number and total capacity	2. 15,000.		
Used all together, or in series	Together.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	None.		
Quantity	Do.		
How added	Do.		
FILTERS.			
Number and total area	Do.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.

Appendix 4.

ARDSLEY URBAN DISTRICT.—HOYLE MILL WORKS.

Date completed and brought into operation	
Engineer	Mr. Jos. Latham, Barnsley.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 200 houses drained.
Average daily flow of sewage in dry weather	About 3,500 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. No.
Number of water closets in area drained	7
LAND.	
Total area	
Whether underdrained, and how?	Yes.
Nett area upon which sewage can be treated	One acre for effluent by gravitation.
TANKS.	
Number and total capacity	
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 5 tons per year.
How added	Basket in mixing channel.
FILTERS.	
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	About 7 times.
COST OF—	
Land	
Laying out of land	
Tanks	
Filters	

	1895.	1896.	1897.

ARDSLEY EAST AND WEST URBAN DISTRICT.—TINGLEY SEWAGE WORKS.

Appendix 4

Date completed and brought into operation	1893.
Engineer	Frank Massie, Esq., C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	183 houses.
Average daily flow of sewage in dry weather	18,252.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. From buildings.
Number of water-closets in area drained	10.
LAND.	
Total area	2 acres.
Whether underdrained, and how?	Part underdrained with land tiles 4 feet below surface.
Nett area upon which sewage can be treated	2 acres.
TANKS.	
Number and total capacity	2. 1,512 cubic feet.
Used all together, or in series	Both ways.
Whether flow of sewage continuous, or time allowed for settlement	Do.
CHEMICALS.	
Nature	None
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One on line of sewer.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	75 per cent.

ARDSLEY EAST AND WEST URBAN DISTRICT.—THE FALL SEWAGE WORKS.

Date completed and brought into operation	1888.
Engineer	Arthur Fawcett, Esq., C.E. The additions by Frank Massie, Esq., [C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	380 houses.
Average daily flow of sewage in dry weather	36,430 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed. From buildings.
Number of water closets in area drained	30.
LAND.	
Total area	Two acres in 1894. 3 acres 9 perches was added.
Whether underdrained, and how?	Part underdrained with land tiles about 3 feet 6 inches below surface.
Nett area upon which sewage can be treated	4 acres.
TANKS.	
Number and total capacity	5 tanks, 11,232 cubic feet.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed.
CHEMICALS.	
Nature	Lime.
Quantity	15 cwts. per week.
How added	Through mixer by wind mill and water wheel.
FILTERS.	
Number and total area	3. 1,800 cubic feet.
Construction	Coke and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. No.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	At works one.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable.
Proportion of flow in sewer to average flow when storm overflows begin to act	75 per cent.

CALVERLEY URBAN DISTRICT.—CALVERLEY SEWAGE WORKS.

Date completed and brought into operation	Not yet complete. Have been in partial operation since 8th Feb. [1898.
Engineer	Mr. George Riley, Surveyor to the Council.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	30 to 40 acres. 440 houses.
Average daily flow of sewage in dry weather	15,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes.
Number of water closets in area drained	26.
LAND.	
Total area	About 2 acres.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	Filtration not irrigation adopted.
TANKS.	
Number and total capacity	2. 3,900 cubic feet.
Used all together, or in series	Altogether.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 28 lbs. per day.
How added	Blocks placed in the current.
FILTERS.	
Number and total area	3,240 square feet.
Construction	12 inch of 2 inch clinker, 9 inch of ½ inch do., 9 inch of ⅜ and 6 inch of ¼ do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	2. On outfall.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	About one-twelfth.
COST OF—	
Land	Rented (farm of over 31 acres £100 per annum.)

DODWORTH URBAN DISTRICT.—DODWORTH SEWAGE WORKS.

Date completed and brought into operation	May, 1893.
Engineer	Mr. John Wade, Pitt Street, Barnsley.
Whether sanctioned by L.G.B.	Yes. Date of sanction September 10th, 1891.
Area and population or number of houses drained	Area 1,916 acres. Population (in 1891) 3,106.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included ?	Domestic sewage. Surface water not included.
Number of water closets in area drained	12.
LAND.	
Total area	11 acres, of which about 2½ acres are laid out for the treatment of sewage.
Whether underdrained, and how ?	
Nett area upon which sewage can be treated	11 acres.
TANKS.	
Number and total capacity	Two tanks.
Used all together, or in series	One at a time.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settlement in tank.
CHEMICALS.	
Nature	None used.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	2½ acres are laid out in beds with drains.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Four.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	The land is leased by the District Council at an annual rent of £44.
Laying out of land; Tanks; Filters	(2½ acres). £963.

SLUDGE.	1895.	1896.	1897.
Amount			
How dealt with			
Cost, or			
Return			

PRODUCE. Crops; Value; **WORKING EXPENSES.** Labour; Chemicals; Pumping	The Sewage Farm was for a year or two from the commencement let to a neighbouring farmer, who paid the Council a rent of £10 a year, and undertook at his own expense the management of the farm, but for some years now it has been let to him *free of rent*, and he undertakes the management as before.

Appendix 4.

ELLAND URBAN DISTRICT.—ELLAND SEWAGE WORKS.

Date completed and brought into operation	13th November 1897.
Engineer	M. Paterson, Esq., Bradford.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	10,000 population.
Average daily flow of sewage in dry weather	750,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and trade. Yes.
Number of water closets in area drained	About 350.
LAND.	
Total area	12 acres.
Whether underdrained, and how?	Underdrained with tiles.
Nett area upon which sewage can be treated	About 11 acres.
TANKS.	
Number and total capacity	8 tanks. 600,000 gallons.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Lime and alumino-ferric.
Quantity	About 10 grains to 1 gallon.
How added	Lime is added in milk of lime, alumino-ferric in block.
FILTERS.	
Number and total area	11 acres.
Construction	Land filtration.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	6.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	Cannot say. Never seen them act in the heaviest storm, only when sewer was blocked.
COST OF—	
Land	Rented.
Laying out of land	£3,470.
Tanks	1,000.
Filters

Appendix 4.

EMLEY URBAN DISTRICT.—SMITH'S QUARRY OR BROOM HALL SEWAGE WORKS.

Date completed and brought into operation	In use about two years.
Engineer	Nil.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	72, about. Population about 360.
Average daily flow of sewage in dry weather	Not gauged.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes.
Number of water closets in area drained	None.
LAND.	
Total area	About 9 acres.
Whether underdrained, and how?	Yes. I believe by pipes.
Nett area upon which sewage can be treated	About 7 acres.
TANKS.	
Number and total capacity	4 tanks.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alum-ferric tablets.
Quantity	As required.
How added	In chambers.
FILTERS.	
Number and total area	We are now constructing bacteria tanks on Dibdin's system, which will be completed in a short time and the old tanks done away with.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	Not gauged.

HANDSWORTH URBAN DISTRICT.—SOAP HOUSE LANE, WOODHOUSE, SEWAGE WORKS.

(District No. 2.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 2,900.
Average daily flow of sewage in dry weather	34,800 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, and effluent from tannery.
Number of water closets in area drained	5 water-closets and several waste water-closets.
LAND.	
Total area	5 acres 2 roods 17 perches.
Whether underdrained, and how?	Subsoil drainage with sanitary pipes.
Nett area upon which sewage can be treated	4 acres 3 roods 9 perches.
TANKS.	
Number and total capacity	6 tanks hold 51,800 gallons.
Used all together, or in series	Three alternately.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric and lime.
Quantity	
How added	
FILTERS.	
Number and total area	Four filters in course of construction.
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	Storm overflows not been required to act to the present.
COST OF—	
Land	£691 13 2.
Laying out of land	£435 17 0.
Tanks	£330 16 2.
Filters	Not completed.

HANDSWORTH URBAN DISTRICT.—SOAP HOUSE LANE, WOODHOUSE MILL, SEWAGE WORKS. (District No. 1.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 1,250.
Average daily flow of sewage in dry weather	15,000 gallons in 24 hours.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Only from yards and roofs of houses.
Number of water closets in area drained	One.
LAND.	
Total area	1 acre 2 roods 29 perches.
Whether underdrained, and how?	Subsoil drainage with sanitary pipes.
Nett area upon which sewage can be treated	The whole.
TANKS.	
Number and total capacity	One tank, holds 26,600 gallons.
Used all together, or in series	Together.
Whether flow of sewage continuous, or time allowed for settlement	Intermittent.
CHEMICALS.	
Nature	Lime and alumino-ferric.
Quantity	One cwt. of each per day.
How added	The lime diluted with water before mixing, the alumino-ferric placed under the outfall pipe of pump.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Do.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—	
Land	£355 18 2
Laying out of land	£120 0 0
Tanks	£170 0 0
Filters	None.

	1895.	1896.	1897.
SLUDGE.			
Amount			100 tons per annum.
How dealt with			Given away.

Appendix 4.

HANDSWORTH URBAN DISTRICT.—GREENWOOD LANE, WOODHOUSE, SEWAGE WORKS.

(District No. 2*a*.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 300.
Average daily flow of sewage in dry weather	3,600 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. To a very small extent (roofs and yards.)
Number of water closets in area drained	Two.
LAND.	
Total area	1 acre.
Whether underdrained, and how?	Subsoil drains with sanitary pipes.
Nett area upon which sewage can be treated	1 acre.
TANKS.	
Number and total capacity	One tank, capacity 10,000 gallons, 2 filters (originally two pre cipitation tanks.)
Used all together, or in series	Tank continuous. Filters alternately.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Very small.
How added	Placed in inlet to tank.
FILTERS.	
Number and total area	Two.
Construction	Coke breeze and gravel.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittent, on Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed front weir
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£100 0 0
Laying out of land	£115 16 7
Tanks	£81 12 7
Filters	About £30 0 0

Appendix 4.

HANDSWORTH URBAN DISTRICT.—CALVERT ROAD, WOODHOUSE, SEWAGE WORKS.

(District No. 3.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 290.
Average daily flow of sewage in dry weather	3,480 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Entirely domestic. Only yards and roofs.
Number of water closets in area drained	None.
LAND.	
Total area	0 acres 3 roods 32 perches.
Whether underdrained, and how?	Subsoil pipes throughout.
Nett area upon which sewage can be treated	0 acres 3 roods 32 perches.
TANKS.	
Number and total capacity	One.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Very small.
How added	In outfall sewer at tank.
FILTERS.	
Number and total area	Two.
Construction	Large and small coke.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently, on Dibdin's system
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Front weir.
Proportion of flow in sewer to average flow when storm overflows begin to act

HANDSWORTH URBAN DISTRICT.—NORMANTON HILL SEWAGE WORKS.
(District No. 4.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 1,655.
Average daily flow of sewage in dry weather	19,860 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic.
Number of water closets in area drained	None.
LAND.	
Total area	4 acres 0 roods 26 perches.
Whether underdrained, and how?	Subsoil drains, sanitary pipes.
Nett area upon which sewage can be treated	4 acres.
TANKS.	
Number and total capacity	Four. Capacity 23,000 gallons.
Used all together, or in series	Used together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	One cwt. per diem.
How added	In chamber at tank head.
FILTERS.	
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method

HANDSWORTH URBAN DISTRICT.—HOLLINSEND, INTAKE, AND GLEADLEY SEWAGE WORKS.

(District No. 8.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 2,800.
Average daily flow of sewage in dry weather	33,840 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Only yards and roofs.
Number of water closets in area drained	Three.
LAND.	
Total area	4 acres.
Whether underdrained, and how?	Subsoil drains with sanitary pipes.
Nett area upon which sewage can be treated	3 acres 1 rood 20 perches.
TANKS.	
Number and total capacity	Six. Capacity 40,000 gallons.
Used all together, or in series	In series of three.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Rather more than 1 cwt. per diem.
How added	In chamber at tank head.
FILTERS.

HANDSWORTH URBAN DISTRICT.—RICHMOND AND BRITTON HILL SEWAGE WORKS.

(District No. 7.)

Date completed and brought into operation	At the end of 1896.
Engineer	W. H. Lancashire, C.E., Sheffield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 220.
Average daily flow of sewage in dry weather	2,640 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic (surface water excluded).
Number of water closets in area drained	Five.
LAND.	
Total area	One acre.
Whether underdrained, and how?	Subsoil drains.
Nett area upon which sewage can be treated	0 acres 3 roods 20 perches.
	NOTE.—A further area of 0 acres 3 roods 25 perches has been recently purchased.
TANKS.	
Number and total capacity	Two. Capacity 16,800 gallons.
Used all together, or in series	Together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Small.
How added	In outfall pipe.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—

Appendix 4.

HECKMONDWIKE URBAN DISTRICT.—HECKMONDWIKE SEWAGE WORKS.

(Farm situate in the Borough of Dewsbury.)

Date completed and brought into operation	6th April 1896.
Engineer	James Saville, Town's Surveyor, Heckmondwike.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	697 acres. 2,384 houses. Population about 11,000.
Average daily flow of sewage in dry weather	Estimated to be 350,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mostly domestic. 1 large brewery and a few manufactories connected. Large portion of surface water included.
Number of water closets in area drained	About 630.
LAND.	
Total area	37½ acres, 31½ being available by gravitation.
Whether underdrained, and how?	15 inch to 9 inch main effluent full length of sand. 9 inch and 6 inch under drains to beds, open joints, rubble stone 1 ft. above pipes, laid at depths 6 to 8 ft. below surface of beds.
Nett area upon which sewage can be treated	28½ acres.
TANKS.	
Number and total capacity	Three.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Do.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works Construction—whether fixed side weirs, leaping weirs, or adjustable valves Proportion of flow in sewer to average flow when storm overflows begin to act	1 at the end of main outfall sewer to flow over when 21 inch pipes are half full. 1 on the line of main outfall sewer to flow over when 21 inch pipes are two-thirds full. Main outfall sewer 21 inch pipes are half full at outfall end when the pipes are fully charged at the Town end. Main outfall about 1½ miles long. Storm overflows in various sewers. Leaping weirs, set to throw when sewer runs more than in slight rains.
COST OF—	
Land	About £150 per acre.
Laying out of land	£3,200.
Tanks	£500.

HORBURY URBAN DISTRICT.—HORBURY SEWAGE WORKS.

Date completed and brought into operation	The sewage works were brought into operation on the 28th [December, 1895.
Engineer	Sam Shaw, Esq., Dewsbury.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 1,300 houses are drained.
Average daily flow of sewage in dry weather	Approximate average daily flow of sewage is 136,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and trade sewage combined. Surface water is included.
Number of water closets in area drained	About 45 water-closets are drained into sewers.
LAND.	
Total area	17 acres 3 roods and 39 perches.
Whether underdrained, and how?	11 acres of above is underdrained by 18, 15, 12 and 9 inch pipes, also 4 inch tile drains.
Nett area upon which sewage can be treated	11 acres 2 roods and 27 perches.
TANKS.	
Number and total capacity	3 settling tanks. Total capacity 190,000 gallons.
Used all together, or in series	Used all together.
Whether flow of sewage continuous, or time allowed for settlement	Flow of sewage continuous.
CHEMICALS.	
Nature	No chemicals used at present.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	4 sludge filters, total area of same 678 square yards.
Construction	The sludge filters are constructed of 2 in. and 4 in. tile drain, and covered with filtering material to the depth of 2 ft. as follows:—12 in. broken bricks, 6 in. screened clinker ashes, and 6 in. fine ashes.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Used intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None on line of sewers. One at sewage works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	The level of weir is fixed at $\frac{2}{3}$ diameter of sewer.
COST OF—	
Land	11 acres 2 roods 27 perches now in use is leased from Horbury Common Land Trustees for 50 years at 50*l*. per annum, and 6 acres 1 rood and 12 perches not in use cost 1,250*l*.
Laying out of land	Cost 263*l*. 1*s*. 0*d*.
Tanks	The settling tanks cost 494*l*. 8*s*. 8*d*.
Filters	2 sludge filters in contract cost 61*l*. 12*s*. 0*d*., and 2 do. cost 101*l*. 6*s*. 2*d*. done by Council's men.

	1895.	1896.	1897.
SLUDGE.			
Amount	The average amount of sludge we obtain is 30 loads per week (dry)		
How dealt with	The sludge is given to farmers on condition they cart same away.		
Cost, or			
Return			
PRODUCE.			
Crops	The sewage farm is not cultivated.		
Value	Do.		
WORKING EXPENSES.			
Labour	The working expenses of the sewage farm are on an average 350*l*. per annum.		
Chemicals	Do.		
Pumping	Do.

Appendix 4.

HOYLAND NETHER URBAN DISTRICT.—ELSECAR SEWAGE WORKS.

Date completed and brought into operation	January, 1897.
Engineer	William Farrington.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Area of District 2,084 acres.
Average daily flow of sewage in dry weather	Population 13,000.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water partly included.
Number of water closets in area drained	Not more than 12 water closets.
LAND.	
Total area	12 acres.
Whether underdrained, and how?	Yes. 6 inch pipes and 4 inch field tiles, about 4 feet deep.
Nett area upon which sewage can be treated	11 acres.
TANKS.	
Number and total capacity	Nine. 113,906 gallons.
Used all together, or in series	Both.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Spence's alumino-ferric.
Quantity	About 1 ton per month.
How added	In cage in mixing race.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Five.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	Sewer about ¾ full before overflows act.
COST OF—	
Land	£1,000.
Laying out of land	Total cost of works £2,830.
Tanks	
Filters

Appendix 4.

ILKLEY URBAN DISTRICT.—ILKLEY SEWAGE WORKS.

Date completed and brought into operation	November, 1898. (After extensions and alterations.)
Engineer	John Waugh, C.E., Bradford.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,210 houses drained.
Average daily flow of sewage in dry weather	About 450,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. One laundry and one brewery. Surface water is included.
Number of water closets in area drained	1,255, and about 170 waste water closets.
LAND.	
Total area	Nine acres.
Whether underdrained, and how?	Earthenware subsoil drains.
Nett area upon which sewage can be treated	6⅓ acres.
TANKS.	
Number and total capacity	Five tanks. 170,000 gallons.
Used all together, or in series	May be used either way.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	150 lbs. per day.
How added	Automatic chemical mixer. (Pratt's patent.)
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Several on line of sewers and one at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Three fixed weirs and the rest adjustable valves.
Proportion of flow in sewer to average flow when storm overflows begin to act	Overflows at ¾ diameter of sewer.
COST OF—	
Land	The original scheme was carried out in 1876, and recent extensions have been carried out at a cost of £2,000, exclusive of value of land purchased under original scheme. No particulars easily available as to cost of original scheme, or how separated, except the total amount borrowed in 1876–7 was £15,000 for works of sewerage and sewage disposal.

Appendix 4.

ILKLEY URBAN DISTRICT.—BEN RHYDDING SEWAGE WORKS.

Date completed and brought into operation	November, 1898.
Engineer	John Waugh, C.E., Bradford.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,300 acres. 1,000 population.
Average daily flow of sewage in dry weather	Not been gauged yet.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water is excluded.
Number of water closets in area drained	255.
LAND.	
Total area	Eight and a half acres.
Whether underdrained, and how?	Subsoil drains under banks.
Nett area upon which sewage can be treated	Six acres.
TANKS.	
Number and total capacity	Tanks in duplicate. 30,000 gallons each.
Used all together, or in series	May be used either way.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settlement.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	50 lbs. per day.
How added	By automatic chemical mixer.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One, on line of sewers.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	Overflows at $\frac{3}{4}$ diameter of sewer.
COST OF—	
Land	£1,300.
Laying out of land	£1,268.
Tanks	£480.
Filters

MEXBOROUGH URBAN DISTRICT.—MEXBOROUGH SEWAGE WORKS.

Date completed and brought into operation	1887.
Engineer	Mr. G. White, A.M.I.C.E., Mexborough.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Area 1,293 acres. Population estimated 10,000.
Average daily flow of sewage in dry weather	80 to 90,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included ?	Domestic. Yes.
Number of water closets in area drained	About 50.
LAND.	
Total area	$3\frac{1}{2}$ acres.
Whether underdrained, and how ?	Underdrained.
Nett area upon which sewage can be treated	$3\frac{1}{4}$ acres.
TANKS.	
Number and total capacity	Nine. 257,236 gallons (deduct 20,000 gallons, one tank used as a bacteriological filter).
Used all together, or in series	Series of 3.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settlement.
CHEMICALS.	
Nature	Alumino-ferric, originally black ash.
Quantity	About 6 to 8 grains to the gallon.
How added	Cakes placed in main sewage channel.
FILTERS.	
Number and total area	One of the above tanks 20 feet 0 inch × 22 feet 6 inch, 450 superficial feet turned into filter.
Construction	7 feet 6 inches deep coke breeze, aerated by ventilating pipes.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Dibdin's, continuous.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Three on line of sewers.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	12 inch pipe overflows, two on 18 inch main, one on 15 inch main.
COST OF—	
Land	
Laying out of land	
Tanks	
Filters	

	1895–6.	1896–7.	1897–8.

NORTH BIERLEY URBAN DISTRICT.—NORTH BIERLEY SEWAGE WORKS. Appendix 4.

Date completed and brought into operation	1880.		
Engineer	John Cook.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	4,308 acres. 22,753 population, or 5,890 houses drained.		
Average daily flow of sewage in dry weather	1,000,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, mixed with trade refuse. Surface water included.		
Number of water closets in area drained	285.		
LAND.			
Total area	18 acres.		
Whether underdrained, and how?	2 acres underdrained, 2 acres pit hill shale levelled 5 feet deep and soiled and undrained, and 6 acres buildings and sludge beds.		
Nett area upon which sewage can be treated	10 acres upon which sewage can be treated.		
TANKS.			
Number and total capacity	18 tanks. 200,000 gallons.		
Used all together, or in series	Used all together.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.		
CHEMICALS.			
Nature	Lime and alumino-ferric.		
Quantity	80 tons of alumino-ferric and 160 tons of lime per year.		
How added	Lime added as milk of lime, alumino-ferric in cakes.		
FILTERS.			
Number and total area	None. Effluent from tanks run on to land, except a recently levelled shale hill now acts as a filter.		
Construction			
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method			
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	3 on line of sewers and one at outfall works.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	3 on line of sewers side weirs, and at outfall works leaping weir.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Acts when ¾ full.		
COST OF—			
Land	(And Easement) £5,258 18s. 0d.		
Laying out of land	About £300.		
Tanks	(And Buildings) £3,192 19s. 5d.		
Filters			
	1895.	**1896.**	**1897.**
SLUDGE.			
Amount	About 4,000 cubic yards yearly.		
How dealt with	Wet sludge run on to drained sludge beds, and allowed to dry, when dry carted away on to agricultural land &c., by farmers, at a cost of £100 a year.		
Cost, or			
Return			
PRODUCE.			
Crops	Grass and after grass.

OSSETT BOROUGH URBAN DISTRICT.—HEALEY SEWAGE WORKS.

Date completed and brought into operation			
Engineer	Malcolm Paterson.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained			
Average daily flow of sewage in dry weather	65,000 gallons per 12 hours.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, trade refuse, and storm water.		
Number of water closets in area drained			
LAND.			
Total area	About $1\frac{1}{2}$ acres.		
Whether underdrained, and how?	Underdrained.		
Nett area upon which sewage can be treated	$1\frac{1}{2}$ acres.		
TANKS.			
Number and total capacity	Three tanks. 50,000 gallons.		
Used all together, or in series			
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Milk of lime and alumino-ferric blocks.		
Quantity			
How added	Lime, water-wheel.		
FILTERS.			
Number and total area	No filters.

OTLEY URBAN DISTRICT.—OTLEY SEWAGE WORKS.

Date completed and brought into operation	1893.		
Engineer	Messrs. Brierley & Holt, Blackburn.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	1,800 houses. Population 8,400.		
Average daily flow of sewage in dry weather	180,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed, domestic and trade, mixed. Yes.		
Number of water closets in area drained	300.		
LAND.			
Total area	8 acres.		
Whether underdrained, and how?	Yes. Tiles 6 inches apart.		
Nett area upon which sewage can be treated	5 acres.		
TANKS.			
Number and total capacity	4. 160,000 gallons.		
Used all together, or in series	Intermittently used in series		
Whether flow of sewage continuous, or time allowed for settlement	Time allowed.		
CHEMICALS.			
Nature	Alumino-ferric.		
Quantity	½ cwt. per day.		
How added	Placed in cuffling wire		
FILTERS.			
Number and total area	None.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works			
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weirs.

OXENHOPE URBAN DISTRICT.—OXENHOPE SEWAGE WORKS.

Date completed and brought into operation	November, 1897.
Engineer	Barber Hopkinson & Co., Keighley.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	240 houses drained.
Average daily flow of sewage in dry weather	15,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. No road water, but eaves water where tipper closets are used.
Number of water closets in area drained	55.
LAND.	
Total area	11 acres 2 roods 38 perches.
Whether underdrained, and how?	Not underdrained.
Nett area upon which sewage can be treated	7 acres 2 roods 0 perches.
TANKS.	
Number and total capacity	One. 15,000 gallons.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	
Quantity	
How added	
FILTERS.	
Number and total area	Two in use, and two in course of construction. The total area is 398 square yards.
Construction	Broken stone and coke breeze.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—	
Land	£1,650.

QUEENSBURY URBAN DISTRICT.—QUEENSBURY SEWAGE WORKS.

Date completed and brought into operation	1895. (Information not supplied by Authority.)
Engineer	John Drake.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	6,740 population. 1,471 acres.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Yes.
Number of water closets in area drained	
LAND.	
Total area	
Whether underdrained, and how?	3 acres of land. I.D.F.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	Eleven tanks.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	
How added	Put into channel
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Several on line of sewers. One at outfall works.

Appendix 4.

RAVENSTHORPE URBAN DISTRICT.—RAVENSTHORPE SEWAGE WORKS.

Date completed and brought into operation	1876.
Engineer	Malcolm Paterson, C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	375 acres. Population 5,500. No. of houses 1,350.
Average daily flow of sewage in dry weather	160,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic.
Number of water closets in area drained	100.
LAND.	
Total area	14 acres.
Whether underdrained, and how?	Partially. Pipes.
Nett area upon which sewage can be treated	6 acres 3 roods 23 perches.
TANKS.	
Number and total capacity	Three. Capacity 38,250 gallons.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Continuous when pumping.
CHEMICALS.	
Nature	Lime as milk of lime.
Quantity	36 tons per annum.
How added	By lime mixer to carrier.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One on sewer.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weir.
Proportion of flow in sewer to average flow when storm overflows begin to act	When tank sewer overflows.

Appendix 4.

RAWDON URBAN DISTRICT.—RAWDON SEWAGE WORKS.

Date completed and brought into operation	1897.
Engineer	William Henry Radford, Nottingham.
Whether sanctioned by L.G.B.	The plans and scheme were sanctioned by L.G.B.
Area and population or number of houses drained	14,059 acres. Population 3,077.
Average daily flow of sewage in dry weather	About 50,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Almost entirely domestic. Excluded as much as possible.
Number of water closets in area drained	Not known exactly.
LAND.	
Total area	15 acres.
Whether underdrained, and how?	Drained with land tiles. Drains 5 feet deep, 7 yards apart.
Nett area upon which sewage can be treated	12 acres.
TANKS.	
Number and total capacity	6 tanks each 20 × 20 feet × 6 feet deep.
Used all together, or in series	Used in two sets of 3 each.
Whether flow of sewage continuous, or time allowed for settlement	A continuous flow through one set of tanks until there is a fair amount of deposit, when they are drawn off and the other set put in use.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 10 to 12 grains to a gallon.
How added	It is dissolved in a large tub, from which a continuous stream is sprinkled into the sewage as it leaves the outfall pipe.
FILTERS.	
Number and total area	After chemical precipitation the sewage flows on the land for filtration.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	2 fixed in manholes.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	A 12-inch pipe is filled to a depth of 10 inches before it flows over the storm weir.
COST OF—	
Land	£4,446.
Laying out of land Tanks Filters	Mixed up with other items in contract. Over £18,000 have been expended on the scheme already, and various extensions are now required.

	1895.	1896.	1897.
SLUDGE.			
Amount How dealt with Cost, or Return	We have an excellent lime mixing machine, but as we do not need to use lime at present, we have very little sludge, and the little we have can be dealt with on our own land for years to come, as the land is of a very sandy nature.		
PRODUCE.			
Crops	Turnips, potatoes, cabbages, &c.		
Value			
WORKING EXPENSES.			
Labour	For treatment not separated from other costs in connection [with sewag		
Chemicals	18 to 20 pounds.		
Pumping	None.

Appendix 4.

ROTHWELL URBAN DISTRICT.—LEMONROYD SEWAGE WORKS.

Date completed and brought into operation	July, 1898.
Engineer	Sam Shaw, Dewsbury.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,708 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Partly.
Number of water closets in area drained	
LAND.	
Total area	20 acres.
Whether underdrained, and how?	Yes. 4 inch pipes.
Nett area upon which sewage can be treated	18 acres.
TANKS.	
Number and total capacity	9. 26,000 gallons.
Used all together, or in series	In series of 3.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	Alumino-ferric and lime.
Quantity	½ ton alumino-ferric per week.
How added	Alumino-ferric in box of outfall channel, lime mixed with engine.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	1 on line of sewers and 1 at outfall.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Movable boards
Proportion of flow in sewer to average flow when storm overflows begin to act	Two-thirds.
COST OF—	
Land	£7,000.

SOOTHILL NETHER URBAN DISTRICT.—SOOTHILL NETHER SEWAGE WORKS.

Date completed and brought into operation	1893.		
Engineer	Malcolm M. Paterson, C.E., Bradford.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	562 acres. Population about 5,900.		
Average daily flow of sewage in dry weather	150,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and trade effluent. Surface water not included.		
Number of water closets in area drained	70.		
LAND.			
Total area	5 acres.		
Whether underdrained, and how?	Underdrained with 3 inch dry socketed pipes.		
Nett area upon which sewage can be treated	3½ acres.		
TANKS.			
Number and total capacity	Three. Total capacity 147,200 gallons.		
Used all together, or in series	Series.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Alumino-ferric and lime.		
Quantity	2 tons in 3 months lime and alumino-ferric.		
How added	By lime mixer driven by flow of sewage and alumino-ferric put into channels.		
FILTERS.			
Number and total area	For drying sludge only.		
Construction			
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method			
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Seven.

THORNHILL URBAN DISTRICT.—THORNHILL SEWAGE WORKS.

Date completed and brought into operation	April, 1894.		
Engineer	Sam. W. Parker.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	About 1,700 houses.		
Average daily flow of sewage in dry weather	About 200,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic only. Roofs only.		
Number of water closets in area drained	70 to 80.		
LAND.			
Total area	12 acres.		
Whether underdrained, and how?	Underdrained with 4 inch land tiles.		
Nett area upon which sewage can be treated	7 acres.		
TANKS.			
Number and total capacity	Two series of 7 tanks. Total capacity 325,000 gallons.		
Used all together, or in series	Used together, except when one set are being cleaned.		
Whether flow of sewage continuous, or time allowed for settlement	The sewage is pumped through the tanks in about 4 hours.		
CHEMICALS.			
Nature	Alumino-ferric and lime.		
Quantity	8 grains alumino-ferric. 2 grains lime (milk) per gallon.		
How added	Alumino-ferric blocks placed in chemical chamber, and sewage pumped on to it, the lime is made into milk of lime and mixed with sewage in the pump well.		
FILTERS.			
Number and total area	None.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	One on line of sewers, and one at outfall works.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable valves and penstock valve.

THURLSTONE URBAN DISTRICT.—THURLSTONE SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	Formally opened 22nd October, 1897.
Engineer	T. A. Murray, C.E. (Sheffield).
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Area about 1,000 acres. Population 2,000. Houses 300.
Average daily flow of sewage in dry weather	80,000 gallons per day.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed. Surface water excluded.
Number of water closets in area drained	About six.
LAND.	
Total area	7½ acres.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	6 acres divided into 14 plots.
TANKS.	
Number and total capacity	Two, holding 15,000 gallons.
Used all together, or in series	Together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric, but none used up to the present.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	None. The system being intermittent land filtration.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	During storms the outflow into settling tanks is increased by at least ¾ the normal average flow, and completely filling the pipes.
COST OF—	
Land	£923.
Laying out of land	£400.
Tanks	£276.
Filters	

	1895.	1896.	1898.
SLUDGE.			
Amount			4 cart loads per month.
How dealt with			Used on sewage farm plots for tillage purposes.
Cost, or			
Return			
PRODUCE.			
Crops	Oats, cabbages, cauliflowers, peas, celery, and other market garden produce.		
Value	Only 2 or 3 of the plots on the sewerage farm have, during 1898, been cultivated. When the whole of the land is utilized, it is expected to produce what will cover working expenses.		
WORKING EXPENSES.			
Labour			£100 per year (estimated).
Chemicals			Nil.
Pumping			Nil.

HEMSWORTH RURAL DISTRICT.—SOUTH KIRKBY SEWAGE WORKS.

Date completed and brought into operation	Summer, 1895.		
Engineer	T. H. Richardson.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained			
Average daily flow of sewage in dry weather			
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only.		
Number of water closets in area drained	Two W.C's.		
LAND.			
Total area	2 acres.		
Whether underdrained, and how?	Yes. 4-inch unsocketted pipes.		
Nett area upon which sewage can be treated	One acre.		
TANKS.			
Number and total capacity	3 tanks. One 16 feet 0 inch × 16 feet 0 inch, and two 16 fee 0 inch × 10 feet 0 inch. Average depth, 3 feet.		
Used all together, or in series	Used in series.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.		
CHEMICALS.			
Nature	Alumino-ferric.		
Quantity	4 cwts. per week.		
How added	In block in channel.		
FILTERS.			
Number and total area	None.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Do.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.		
COST OF—			
Land	(And easements) £351 11*s*. 0*d*.

Appendix 4.

HEMSWORTH RURAL DISTRICT.—MIDDLECLIFFE SEWAGE WORKS.

Date completed and brought into operation	1st March, 1899.
Engineer	T. H. Richardson.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	20 houses. Population 100.
Average daily flow of sewage in dry weather	2,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage only. Water from back yards and roofs admitted.
Number of water closets in area drained	None.
LAND.	
Total area	3 roods 21 perches.
Whether underdrained, and how?	Yes. 4-inch unsocketted pipes.
Nett area upon which sewage can be treated	2 roods.
TANKS.	
Number and total capacity	2 tanks. One 16 feet 0 inch × 14 feet 0 inch, and one 14 feet 0 inch × 12 feet 0 inch. Each 3 feet deep.
Used all together, or in series	Used in series.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Do.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.

KEIGHLEY RURAL DISTRICT.—STEETON SEWAGE WORKS.

Date completed and brought into operation	July, 1896.
Engineer	Barber Hopkinson & Co. Keighley.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	309 houses.
Average daily flow of sewage in dry weather	79,200 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage eaves water and some road water.
Number of water closets in area drained	98.
LAND.	
Total area	4 acres 1 rood 2 perches.
Whether underdrained, and how?	Yes. With arthenware pipes th open joints.
Nett area upon which sewage can be treated	2 acres 0 roods 20 perches.
TANKS.	
Number and total capacity	2 tanks. 18,280 gallons.
Used all together, or in series	Used alternately.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settlement.
CHEMICALS.	
Nature	No chemicals.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	None.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at entrance to outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable valve.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	£437 10 0

SKIPTON RURAL DISTRICT.—EARBY SEWAGE WORKS.

Date completed and brought into operation	1896. (Information not supplied by Authority.)
Engineer	
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	610 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade waste.
Number of water closets in area drained	
LAND.	
Total area	7 acres.
Whether underdrained, and how?	3 acres I.D.F.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	2 tanks.
Used all together, or in series	Alternately.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	Do.
Construction	Do.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at outfall wor
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable valves.

Appendix 4.

TADCASTER RURAL DISTRICT.—CROSSGATES, BARWICK-IN-ELMET, SEWAGE WORKS.

Date completed and brought into operation	Completed during the year 1887.
Engineer	Mr. Hodgson Denham.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 260 houses, with a population of 1,300.
Average daily flow of sewage in dry weather	About 13,000 gallons daily.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. From yards only.
Number of water closets in area drained	About 4 W.C.'s.
LAND.	
Total area	¾ of an acre.
Whether underdrained, and how?	Yes. Land tiles 3 inch × 4 inch and 6 inch.
Nett area upon which sewage can be treated	½ of an acre.
TANKS.	
Number and total capacity	
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 4 tons a year.
How added	One cake always standing in stream of sewage.
FILTERS.	
Number and total area	Four. 18 feet square. Each 3 feet deep.
Construction	Built of brick, charged with chequers, coke breeze and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	One each week, allowed 3 weeks for clearing out. Not Dibdin method. Mr. Denham method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One to flow on land only.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	None.
Proportion of flow in sewer to average flow when storm overflows begin to act	About one-third more sewage than ordinary flow is added when wet.
COST OF—	
Land	Loan obtained was 1,500*l.*
Laying out of land	About 100*l.*
Tanks	
Filters	About 123*l.*

	1895.	1896.	1897.

Appendix 4.

TADCASTER RURAL DISTRICT.—KIPPAX SEWAGE WORKS.

Date completed and brought into operation	September 1889.
Engineer	Messrs. Brundall, Simmons and Brundall, and Denham.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	About 699 houses. Population about 2,796.
Average daily flow of sewage in dry weather	About 13,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. No.
Number of water closets in area drained	About 4 W.C.'s.
LAND.	
Total area	About four acres.
Whether underdrained, and how?	About one acre laid with 3 inch land tiles.
Nett area upon which sewage can be treated	Four acres.
TANKS.	
Number and total capacity	Two tanks. 540 feet square. Each 4 feet 6 inches deep.
Used all together, or in series	In series. Changed weekly.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow into one tank until changed. Water drained from tank on land and solids to filter bed.
CHEMICALS.	
Nature	No.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	One filter. 18 feet square, 3 feet deep.
Construction	Coke breeze and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	For straining water from solid sewage. Not on Dibdin's method; Mr. Denham's settling tank.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One line of sewers to works. Two outlets on to land.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	No.
Proportion of flow in sewer to average flow when storm overflows begin to act	About one third more sewage after heavy rains, which gets into sewers from yards.
COST OF—	
Land	Leased for 30 years at £13 a year.
Laying out of land	
Tanks	About £140 and filter included.
Filters	

	1895.	1896.	1897.
SLUDGE.			
Amount			About 1 ton per week.
How dealt with			Spread on land.
Cost, or			No account kept.

Appendix 4.

WAKEFIELD RURAL AND ARDSLEY URBAN DISTRICTS.—WRENTHORPE SEWAGE WORKS.

Date completed and brought into operation	Early in 1897.
Engineer	Frank Massie, Assoc. M. Inst. C. E., Wakefield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	1,000 acres. 5,670 No. of persons.
Average daily flow of sewage in dry weather	No record. Probably 90,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water is excluded as far as it possibly can.
Number of water closets in area drained	Comparatively few. No exact record.
LAND.	
Total area	12 acres 3 roods 30 perches.
Whether underdrained, and how?	The area upon which the tank area is treated is underdrained with subsoil pipe.
Nett area upon which sewage can be treated	4 acres.
TANKS.	
Number and total capacity	Two of Candy's flow tanks, each 14 feet 6 inch diameter.
Used all together, or in series	Separately.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	16 tons per annum.
How added	Blocks are placed in the inlet channel.
FILTERS.	None. Since 9th August 1898, the sewage from 700 persons has been experimentally treated on 3 primary and 3 secondary bacteria beds on the Dibdin system.
Number and total area	
Construction	
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Six.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs
Proportion of flow in sewer to average flow when storm overflows begin to act	No record.
COST OF—	
Land	£2,717.
Laying out of land, Tanks, Filters	£2,565.

	1895.	1896.	1897.
SLUDGE.			
Amount	Not in operation.	Not in operation.	No record.
How dealt with	Allowed to dry in lagoons and then worked into the land.		
Cost, or Return	Not in operation.	Not in operation.	No record.
PRODUCE.			
Crops			Rye grass.
Value			
WORKING EXPENSES.			
Labour			£108.
Chemicals			£40.
Pumping			None.

Appendix 4.

WAKEFIELD RURAL DISTRICT.—NEW JERUSALEM SEWAGE WORKS.

Date completed and brought into operation	1890.		
Engineer	Arthur Fawcett, Assoc.M.Inst.C.E., Wakefield.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	110 acres. 1,000 persons.		
Average daily flow of sewage in dry weather	No exact record, probably 15,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water excluded as far as possible.		
Number of water closets in area drained	Very few.		
LAND.			
Total area	3 acres.		
Whether underdrained, and how?	Yes, but they have since been most blocked up.		
Nett area upon which sewage can be treated	The laying out of the land was never completed. The matter is now before the L.G.B.		
TANKS.			
Number and total capacity	Three. 31,000 gallons.		
Used all together, or in series	Together.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Alumino-ferric.		
Quantity	5 tons per annum.		
How added	Blocks are placed in the inlet channel.		
FILTERS.			
Number and total area	None.		
Construction	Do.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Do.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Do.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.		
COST OF—			
Land	£210.		
Laying out of land	Not yet laid out.

WAKEFIELD RURAL DISTRICT.—NEW SHARLSTON SEWAGE WORKS.

Date completed and brought into operation	
Engineer	
Whether sanctioned by L.G.B.	
Area and population or number of houses drained	100 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic.
Number of water closets in area drained	
LAND.	
Total area	None.
Whether underdrained, and how?	Do.
Nett area upon which sewage can be treated	Do.
TANKS.	
Number and total capacity	Four tanks.
Used all together, or in series	Three all together, and one for another part of sewage.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	?
How added	Placed in channel.
FILTERS.	
Number and total area	6. Total area 14 square feet.
Construction	Coke.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not Dibdin's.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Moveable.
Proportion of flow in sewer to average flow when storm overflows begin to act	?

WORTLEY RURAL DISTRICT.—ECCLESFIELD SEWAGE WORKS.

Date completed and brought into operation	April, 1894.		
Engineer	D. Balfour, Newcastle-on-Tyne, for farm proper; outside works, [G. E. Beaumont, Engineer and Surveyor of District Council.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	4,000 population. No definite area.		
Average daily flow of sewage in dry weather	Summer flow 15 gallons per head.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Surface water admitted from roofs and back yards.		
Number of water closets in area drained	23, three of which are not connected to main sewer.		
LAND.			
Total area	5 acres.		
Whether underdrained, and how?	Yes, by socketted pipes under walks and dividing ridges.		
Nett area upon which sewage can be treated	$3\frac{1}{2}$ acres.		
TANKS.			
Number and total capacity	Two.		
Used all together, or in series	Alternatively, except in wet weather, when both used together.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Alumino-ferric.		
Quantity	About 12 tons annually.		
How added	In slabs in mixing chamber.		
FILTERS.			
Number and total area	No artificial filter except coke cage in each settling tank.		
Construction			
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method			
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	One on line of sewers and one at outfall works.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weir in sewer; penstock or half grate at works.		
Proportion of flow in sewer to average flow when storm overflows begin to act	Half full in sewer and works both.		
COST OF—			
Land	£1,000 exclusive of legal and tenant-right charges.		
Laying out of land	£2,100 inclusive.		
Tanks			
Filters			
	Sept. 30, 1895, to Sept. 30, 1896.	To Sept. 30, 1897.	To Sept. 30, 1898.
SLUDGE.			
Amount	About 50 tons yearly sold, and some dug in.		
How dealt with	Sold to farmer at 6*d.* per load.		
Cost, or			
Return	24*s.*	24*s.*	24*s.*
PRODUCE.			
Crops	Vegetables, ryegrass, and willows.		
Value	£22 0*s.* 5*d.*	£31 15*s.* 11*d.*	*£25 11*s.* 5*d.*
WORKING EXPENSES.			
Labour	One man at 23*s.* per week (house, coal, gas, and water free), assistance (pumping sludge) average 3*s.* per week.		
Chemicals	£35 per annum.		
Pumping	No pumping except of sludge.		

* Over £12 12*s.* 0*d.* outstanding for vegetables, which accounts for reduction in receipts for last period.

Appendix 4.

WORTLEY RURAL DISTRICT.—WADSLEY ASYLUM SEWAGE WORKS.

Date completed and brought into operation	1887.
Engineer	West Riding Surveyor.
Whether sanctioned by L.G.B.	I believe so.
Area and population or number of houses drained	Nearly 2,000 population.
Average daily flow of sewage in dry weather	About 80,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Nearly all domestic. Only a small quantity of surface water included.
Number of water closets in area drained	About 200 W.C.'s.
LAND.	
Total area	Nearly 200 acres.
Whether underdrained, and how?	
Nett area upon which sewage can be treated	39½ acres (irrigation land).
TANKS.	
Number and total capacity	We have two straining tanks, used on alternate days.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.

Appendix 4.

SETTLEMENT OR CHEMICAL PRECIPITATION, FOLLOWED BY ARTIFICIAL FILTRATION.

ARDSLEY URBAN DISTRICT.—ARDSLEY PROPER SEWAGE WORKS.

Date completed and brought into operation	28 May 1896.
Engineer	Mr. T. S. McCallum, Manchester.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population draining to works about 4,000.
Average daily flow of sewage in dry weather	About 14,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Small portion of surface water included.
Number of water closets in area drained	19.
LAND.	
Total area	7 acres.
Whether underdrained, and how?	Not yet executed.
Nett area upon which sewage can be treated	$2\frac{1}{4}$ acres available for effluent by gravitation.
TANKS.	
Number and total capacity	Two tanks. Each 19 feet 0 inch diameter × 13 feet 0 inch deep = 47,000 gallons.
Used all together, or in series	Sometimes together and sometimes singly, according to flow.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	Thirty tons per year.
How added	Basket in mixing channel.
FILTERS.	
Number and total area	No. 4. Each 30 feet × 15 feet = 200 square yards.
Construction	Depth of filtering material about 2 feet 5 inch, top layer sand, next layer polarite and sand mixed, below sand and gravel.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One on sewers and one at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs on sewer and at works.
Proportion of flow in sewer to average flow when storm overflows begin to act	7 to 10 times.
COST OF—	
Land	£1,000.
Laying out of land	Not done yet.
Tanks	About £500.
Filters	About £240 (not including filtering material).

	1895.	1896.	1897.
SLUDGE.			
Amount			
How dealt with	Part run into lagoons, dried and disposed of to farmers as manure, part pumped into large pit to a level land.

Appendix 4.

BATLEY BOROUGH URBAN DISTRICT.—BATLEY SEWAGE WORKS.

Date completed and brought into operation	About August, 1889.
Engineer	Mr. J. W. Horsfield, Borough Engineer.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	2,039 acres. 31,865 population.
Average daily flow of sewage in dry weather	500,000 gallons in 24 hours.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with some trade refuse which finds its way into the sewers. Surface water also, but not all.
Number of water closets in area drained	About 600.
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	Ten. 435,217 gallons.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Lime (best Buxton) and sometimes lime and alumino-ferric.
Quantity	Average, 15 grains per gallon. The latter 7 grains of each per gallon.
How added	Every quarter of an hour through a mixing machine.
FILTERS.	
Number and total area	Eight. 3,528 square feet superficial.
Construction	Square filters charged with live coke 2 feet deep.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not Dibdin's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	At sewer outfall works, one with adjustable valve.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	On line of sewers, 5 fixed side weirs, 2 leaping weirs, 3 adjustable valves. Total 11.
Proportion of flow in sewer to average flow when storm overflows begin to act	About twice the quantity.
COST OF—	
Land	3½ acres. £3,900.
Laying out of land Tanks Filters	£7,212 4*s.* 11*d.*

	1895.	1896.	1897.

Appendix 4.

BINGLEY URBAN DISTRICT.—CULLINGWORTH, No. 2, SEWAGE WORKS.

Date completed and brought into operation	1899. (Information not supplied by Authority.)
Engineer	
Whether sanctioned by L.G.B.	
Area and population or number of houses drained	72 houses.
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse.
Number of water closets in area drained	
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	Large circular Ives tank.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	
Construction	Bed of engine ashes.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Continuously.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—

Appendix 4.

BIRKENSHAW URBAN DISTRICT.—BIRKENSHAW SEWAGE WORKS.

Date completed and brought into operation	Works not yet completed.
Engineer	Wm. Crutchley, C.E., Wakefield.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Area 925 acres. Population 2,479.
Average daily flow of sewage in dry weather	107,460 gallons per 12 hours.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Part surface water.
Number of water closets in area drained	All the water closets are drained (30).
LAND.	
Total area	None.
Whether underdrained, and how?	Do.
Nett area upon which sewage can be treated	Do.
TANKS.	
Number and total capacity	2. Each used separately. 46,850 cubic feet.
Used all together, or in series	Used in series.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settlement.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	12 tons per year.
How added	One cake used per day.
FILTERS.	
Number and total area	One filter. Total area 9,630 cubic feet.
Construction	Broken stones and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not Dibdin's.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One on line at outfall works and three on line of sewers.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act	18 inch pipe, 12 inch full.
COST OF—	
Land	£782 9*s.* 11*d.*
Laying out of land	£4,664 4*s.* 5½*d.* (Laying out of land, Tanks, Filters)
Tanks

Appendix 4.

BIRSTALL URBAN DISTRICT.—BIRSTALL SEWAGE WORKS.

Date completed and brought into operation	August, 1896. Tested 2½ years prior to 1896.
Engineer	William Birch, Manchester.
Whether sanctioned by L.G.B.	No.
Area and population or number of houses drained	1,245 acres. 6,528 population. About 1,800 houses.
Average daily flow of sewage in dry weather	About 150,000.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Chiefly domestic. Yes.
Number of water closets in area drained	About 80.
LAND.	
Total area	2¼ acres.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	None.
TANKS.	
Number and total capacity	4 sludge settling tanks, 9,800 gallons; then 10; one continuous precipitating tank, 50,300 gallons. 95 feet 0 inch × 17 feet 0 inch × 5 feet 0 inch.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric in cakes.
Quantity	20 tons a year.
How added	Dissolved by flood of sewage.
FILTERS.	
Number and total area	2 filters of revolving cloths each 20 yards long and 4½ feet wide revolving on drums once round in 20 minutes.
Construction	Revolving cloths on drums.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Continuously. Birch's method.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One pipe overflow in Kirkgate. One open overflow at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed in Kirkgate. Adjustable valve at outfall works.
Proportion of flow in sewer to average flow when storm overflows begin to act	Twice at least (ordinary rain).
COST OF—	
Land	£2,572 15*s.* 0*d.*
Laying out of land	£461 11*s.* 9*d.* Building fence wall all round and entrance gates.
Tanks	£1,605 7*s.* 1*d.* (Tanks and Filters)

Appendix 4.

BRADFORD COUNTY BOROUGH.—FRIZINGHALL SEWAGE WORKS.

Date completed and brought into operation	1874. (Information not supplied by Authority.)
Engineer	
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	10,776 acres. Population 216,361 (1891).
Average daily flow of sewage in dry weather	19,000,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Yes.
Number of water closets in area drained	
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	No land treatment.
TANKS.	
Number and total capacity	34 tanks. 612,000 gallons.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Ferric-sulphate.
Quantity	
How added	In solution.
FILTERS.	
Number and total area	34 filters.
Construction	1 sand, 1 carbonized night soil, 3 engine ashes, 24 coke breeze, 3 clinkers, and 2 bacteria.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	About 50.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act

Appendix 4.

BRADFORD COUNTY BOROUGH.—SANDY LANE BOTTOM SEWAGE WORKS.

Date completed and brought into operation	1896. (Information not supplied by Authority.)
Engineer	J. H. Cox, Esq.
Whether sanctioned by L.G.B.	
Area and population or number of houses drained	138 houses.
Average daily flow of sewage in dry weather	14,400 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Yes.
Number of water closets in area drained	
LAND.	
Total area	
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	Ives' tank.
Used all together, or in series	
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	
How added	In solution.
FILTERS.	
Number and total area	3 filter tanks. Each 24 feet × 15 feet × 3 feet 6 inches.
Construction	Engine ashes and coal.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. No.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One on sewers. One at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	
Proportion of flow in sewer to average flow when storm overflows begin to act

Appendix 4.

GOLCAR URBAN DISTRICT.—CRIMBLE SEWAGE WORKS.

Date completed and brought into operation	About 16 or 17 years ago.
Engineer	John Hanson & Co.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	162 houses drained to Crimble Works.
Average daily flow of sewage in dry weather	Cannot say.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with refuse. Surface water included.
Number of water closets in area drained	12.
LAND.	
Total area	No land treatment.
Whether underdrained, and how?	Do.
Nett area upon which sewage can be treated	Do.
TANKS.	
Number and total capacity	2 tanks, 28 feet × 20 feet, 2 feet 9 inch deep. 3 tanks, 20 feet × 20 feet, 4 feet 0 inch deep.
Used all together, or in series	All together.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Alumino-ferric and lime.
Quantity	2 cwts. each per day.
How added	Automatically.
FILTERS.	
Number and total area	2 filters. Total area 33 feet × 22 feet. 2 feet deep.
Construction	Coke and tiles.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	Cannot say.

Appendix 4.

HUDDERSFIELD COUNTY BOROUGH.—DEIGHTON SEWAGE WORKS.

Date completed and brought into operation	June, 1893.
Engineer	R. S. Dugdale, C.E.
Whether sanctioned by L.G.B.	No. By special Act of Parliament.
Area and population or number of houses drained	About 9,000 acres with a population of 80,000.
Average daily flow of sewage in dry weather	7,000,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Both domestic and trade refuse. Surface water is included.
Number of water closets in area drained	3,650.
LAND.	
Total area	61 acres. Works and tanks stand on 7½ acres.
Whether underdrained, and how?	
Nett area upon which sewage can be treated	No land filtration.
TANKS.	
Number and total capacity	24 tanks having a total capacity of 211,200 cubic feet.
Used all together, or in series	Used separately.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Lime (Buxton) and Copperas.
Quantity	4·5 grains of lime and 4·0 grains of copperas per gallon on an average.
How added	Lime as thin milk of lime some distance before the copperas.
FILTERS.	
Number and total area	24. Total area 4,464 yards.
Construction	Polarite filters, which are being taken out and replaced by cinder filters worked on Dibdin's method.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	22 on line of sewers and 1 at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Mostly fixed side weirs, remainder are leaping weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act	6 to 1.
COST OF—	
Land	£15,615.
Laying out of land	Works £102,000.
Tanks	
Filters

Appendix 4.

LIVERSEDGE URBAN DISTRICT.—LIVERSEDGE SEWAGE WORKS.

Date completed and brought into operation	26th November, 1885.
Engineer	Charles Gott, C.E.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Liversedge only. Area 2,129 acres 3 roods 12 perches. Population 14,300 (estimated).
Average daily flow of sewage in dry weather	800,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Yes.
Number of water closets in area drained	
LAND.	
Total area	20 acres and 32 perches.
Whether underdrained, and how?	Part underdrained.
Nett area upon which sewage can be treated	9 acres 3 roods 14 perches at present, but some 15 or 16 acres are available.
TANKS.	
Number and total capacity	9 tanks. 15,000 gallons.
Used all together, or in series	Used altogether.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settling.
CHEMICALS.	
Nature	Iron ferris and lime.
Quantity	½ ton per week.
How added	A slight flow from mixing tubs.
FILTERS.	
Number and total area	9. Each 48 feet long × 21 feet wide.
Construction	Coke breeze.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Partly on Dibdin's, but as an experiment.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One at the outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable valves.
Proportion of flow in sewer to average flow when storm overflows begin to act	Cannot say.
COST OF—	
Land	The sewage works, main sewers, buildings, and land cost £40,000 (estimated).
Laying out of land

METHLEY URBAN DISTRICT.—GREEN LANE SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	1893.
Engineer	John Richardson, Esq., M.I.C.E., Methley and Leeds.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	23 houses.
Average daily flow of sewage in dry weather	851 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic. Partially.
Number of water closets in area drained	None.
LAND.	
Total area	22 perches.
Whether underdrained, and how?	Yes. Land drain pipes.
Nett area upon which sewage can be treated	10 perches.
TANKS.	
Number and total capacity	Four. 1,008 cubic feet.
Used all together, or in series	Series.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	None.
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	See above.
Construction	Underdrained and levelled.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Continuously.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	None.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Do.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—	
Land; Laying out of land; Tanks; Filters	Held under lease from J. How. Cost cannot be divided. Total cost of works £5,500.

Appendix 4.

MONK BRETTON URBAN DISTRICT.—DAY'S CROFT SEWAGE WORKS.

Date completed and brought into operation	February, 1894.
Engineer	J. L. Marshall.
Whether sanctioned by L.G.B.	Not laid before L.G.B.
Area and population or number of houses drained	34 houses.
Average daily flow of sewage in dry weather	3,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic only. Only roof water.
Number of water closets in area drained	None.
LAND.	
Total area	½ an acre
Whether underdrained, and how?	Underdrained by a 6 inch pipe drain into which sewage after filtration percolates through the land.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	One settling tank.
Used all together, or in series	3,300 gallons.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	None
Quantity	Do.
How added	Do.
FILTERS.	
Number and total area	2 sets of 2 each. 10½ yards
Construction	Clinkers, coke breeze, and flue dust.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One storm overflow.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Side weir 2 inches high.
Proportion of flow in sewer to average flow when storm overflows begin to act	No record kept. The storm water is only roof water.
COST OF—	
Land	£5 a year on lease.
Laying out of land	
Tanks	} £120.

MONK BRETTON URBAN DISTRICT.—SMITHIES' SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	May, 1898.
Engineer	Wade & Turner, Barnsley.
Whether sanctioned by L.G.B.	Not laid before the L.G.B.
Area and population or number of houses drained	154 houses.
Average daily flow of sewage in dry weather	No record kept.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	All domestic sewage. Surface water included.
Number of water closets in area drained	None.
LAND.	
Total area	½ an acre.
Whether underdrained, and how?	Not drained.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	4 tanks. 17,388 gallons, or 8,694 each set of two.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Flow continuous in each series.
CHEMICALS.	
Nature	Spence's alumino-ferric.
Quantity	No record kept
How added	In a solid block placed in channel.
FILTERS.	
Number and total area	2 sets of 2 each. 34⅔ yards area per set.
Construction	Broken rubble, coke breeze, and sand.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Filters used continuously each set (not Dibdin's method).
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	3 on line of sewer.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	1 at outfall. Weirs 2 to 3 inches high.
Proportion of flow in sewer to average flow when storm overflows begin to act	No record kept.
COST OF—	
Land	£8 per year on lease.
Laying out of land	Cost, including the main outfall sewer only, £912.

Appendix 4.

PONTEFRACT BOROUGH URBAN DISTRICT.—KNOTTINGLEY ROAD SEWAGE WORKS.

Date completed and brought into operation	1881.		
Engineer	Designed by Mr. W. Crutchley, carried out under the Borough [Surveyor.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	4,242 acres. About 13,000 population.		
Average daily flow of sewage in dry weather	340,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and small quantity of trade refuse. Surface water is included.		
Number of water closets in area drained	About 300.		
LAND.			
Total area	5 acres.		
Whether underdrained, and how?	Not underdrained.		
Nett area upon which sewage can be treated	3 acres, but not used for treatment.		
TANKS.			
Number and total capacity	Three. 700,000 gallons.		
Used all together, or in series	Altogether.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Lime.		
Quantity	104 tons per year.		
How added	By hopper, and mixed with sewage by water wheel.		
FILTERS.			
Number and total area	Two. 5,150 superficial feet.		
Construction	Enclosed by brick walls, underdrained by perforated pipes, sand and rubble filtering medium.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Continuously.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Two on line of sewer.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	1 fixed, 1 adjustabl		
Proportion of flow in sewer to average flow when storm overflows begin to act	About 6 times dry weather flow in one case, about 12 times in the other.		
COST OF—			
Land	£880.		
Laying out of land			
Tanks	£2,284 6s. 0d., which includes the construction of a portion of the outfall sewer.		
Filters			
	1895.	1896.	1897.

PUDSEY URBAN DISTRICT.—SMALEWELL SEWAGE WORKS.

Appendix 4.

Date completed and brought into operation	August, 1896.
Engineer	J. H. Rhodes and R. W. Cass.
Whether sanctioned by L.G.B.	There has been a slight departure from plans sanctioned by the L.G.B.
Area and population or number of houses drained	200 acres. Population about 2,000, and 3 mills.
Average daily flow of sewage in dry weather	About 84,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic, and mixed with trade refuse. Partly included.
Number of water closets in area drained	Unable to state definitely.
LAND.	
Total area	5 acres 0 roods 34 perches.
Whether underdrained, and how?	Not underdrained. Falls naturally to beck.
Nett area upon which sewage can be treated	About 1¼ acres by irrigation besides the filter beds.
TANKS.	
Number and total capacity	3 tanks. 115,000 gallons.
Used all together, or in series	Can be used altogether or in series.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed for settlement.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 12 tons per annum.
How added	In mixing race as the flow requires.
FILTERS.	
Number and total area	Nine. 2,000 square yards.
Construction	Ballast 9 inch, rough stone 9 inch, fine stone 9 inch, rough ashes 5 inche thick, fine ashes 10 inch thick.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	One.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Leaping weir. To be altered to automatic.
Proportion of flow in sewer to average flow when storm overflows begin to act	When altered the overflow level will be ⅔rds of the diameter of the sewer.
COST OF—	
Land	£700.
Laying out of land	Not laid out.
Tanks	£508 14 8.
Filters	£446 8 6.

Appendix I.

SHEFFIELD COUNTY BOROUGH.—SHEFFIELD SEWAGE WORKS.

Date completed and brought into operation	1886. (Information not supplied by Authority.)
Engineer	A. G. Alsing.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	
Average daily flow of sewage in dry weather	15,000,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Yes.
Number of water closets in area drained	
LAND.	
Total area	22 acres.
Whether underdrained, and how?	
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	90 tanks. 3,000,000 gallons.
Used all together, or in series	In series.
Whether flow of sewage continuous, or time allowed for settlement	Time allowed.
CHEMICALS.	
Nature	Lime.
Quantity	About 7 grains per gallon.
How added	Mechanical mixers.
FILTERS.	
Number and total area	6 filters.
Construction	Earth bank with coke breeze medium.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Dibdin's.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Several on line of sewers, one at outfall works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs and leaping weirs.
Proportion of flow in sewer to average flow when storm overflows begin to act

UPPERMILL URBAN DISTRICT.—HALLS, UPPERMILL, SEWAGE WORKS. Appendix 4

Date completed and brought into operation	29th July, 1896.
Engineer	Mr. T. S. McCallum, Manchester.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	180 acres. Population about 1,600.
Average daily flow of sewage in dry weather	16,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage. A considerable portion of surface water conveyed to works.
Number of water closets in area drained	15.
LAND.	
Total area	1 acre 0 roods 25 perches.
Whether underdrained, and how?	This portion of work not yet executed.
Nett area upon which sewage can be treated	Nearly 1 acre.
TANKS.	
Number and total capacity	Two tanks. Each 13 feet 3 inch × 9 feet 0 inch deep. 15,000 gallons.
Used all together, or in series	Sometimes together and sometimes singly, according to flow.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	Alumino-ferric at present.
Quantity	
How added	Basket in inlet channel.
FILTERS.	
Number and total area	Two filters. Each 18 feet 0 inch × 15 feet 0 inch = 60 square yards. 40 square yards of cinder filters to be added.
Construction	About 2 feet 5 inch filtering material in centre, made up as follows:—Sand 7 inch, polarite 6 inch, mixed with 4 inch of sand, pea gravel 2 inch, bean gravel 3 inch, walnut gravel 2 inch, boulders 5 inch.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	Two on sewers and two at works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	On sewers practically fixed side weirs, at works one automatic valve and one fixed overflow between tanks and filters.
Proportion of flow in sewer to average flow when storm overflows begin to act	7 to 10 times (all not yet adjusted).
COST OF—	
Land	£650.
Laying out of land	Not done yet.
Tanks	About £350.
Filters	About £200 (not including filtering material).

	1895.	1896.	1897.
SLUDGE.			
Amount			
How dealt with	Run into lagoons, dried and carted away for manure by farmers.

Appendix 4.

WATH-ON-DEARNE URBAN DISTRICT.—WATH SEWAGE WORKS.

Date completed and brought into operation	1892.		
Engineer	The late Mr. H. A. Johnson, of Sheffield.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	2,353 acres. Population 8,238 in 1897.		
Average daily flow of sewage in dry weather	155,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	The sewage is mixed to some extent with trade refuse. Surface water, including roof water, is partially included.		
Number of water closets in area drained	Estimated number 75.		
LAND.			
Total area	Nearly 6½ acres.		
Whether underdrained, and how?	Not underdrained.		
Nett area upon which sewage can be treated	Land very unsuitable. Available area about 5½ acres.		
TANKS.			
Number and total capacity	Four. 27,000 gallons each. Total capacity 108,000 gallons.		
Used all together, or in series	Used in series.		
Whether flow of sewage continuous, or time allowed for settlement	From 2 to 3 hours allowed for settlement.		
CHEMICALS.			
Nature	Alumino-ferric and lime.		
Quantity	20 tons alumino-ferric per annum. 25 tons lime per annum.		
How added	Hand mixed.		
FILTERS.			
Number and total area	5 filters. Total arae 3,600 square feet.		
Construction	Brick and concrete walls, concrete floors, filtering medium gravel and polarite.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not on Dibdin's method.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	8 on line of sewers. 1 at outfall works.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	3 valves. Remainder fixed side weirs.		
Proportion of flow in sewer to average flow when storm overflows begin to act	The overflows begin to act when there is from three to four times the ordinary amount of sewage in sewers.		
COST OF—			
Land	£740 1 1		
Laying out of land	All included in one contract.		
Tanks	All included in one contract.		
Filters	All included in one contract.

SADDLEWORTH RURAL DISTRICT.—GREENFIELD AND FRIEZELAND SEWAGE WORKS.

Date completed and brought into operation	
Engineer	Mr. T. S. McCallum, Manchester.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	Population 1,600.
Average daily flow of sewage in dry weather	16,000 gallons.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic sewage. Portion of surface water conveyed to works.
Number of water closets in area drained	
LAND.	
Total area	$2\frac{1}{2}$ acres.
Whether underdrained, and how?	Not yet executed.
Nett area upon which sewage can be treated	1 acre.
TANKS.	
Number and total capacity	2 tanks. Each 13 feet 0 inch diameter × 9 feet 0 inch deep. 14,931 gallons.
Used all together, or in series	Sometimes together, sometimes singly, according to flow.
Whether flow of sewage continuous, or time allowed for settlement	Continuous flow.
CHEMICALS.	
Nature	Alumino-ferric.
Quantity	About 6 cwt. per week.
How added	Basket in inlet channel.
FILTERS.	
Number and total area	2 beds. Each 17 feet 3 inch × 15 feet 0 inch. 57 square yards.
Construction	About 2 feet 5 inch filtering material in centre, made up as follows:—Sand 7 inch, polarite 6 inch, mixed with sand 4 inch, pea gravel 2 inch, bean gravel 3 inch, walnut gravel 2 inch, boulders 5 inch.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	3 on sewers, 1 at works.
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed weirs on sewers. Automatic arrangement at works.
Proportion of flow in sewer to average flow when storm overflows begin to act	7 to 10 times.

WAKEFIELD RURAL DISTRICT.—ALVERTHORPE SEWAGE WORKS.

Date completed and brought into operation	1889.		
Engineer	Arthur Fawcett, Assoc. M.Inst.C.E., Wakefield.		
Whether sanctioned by L.G.B.	Yes.		
Area and population or number of houses drained	1,017 acres. 5,000 population.		
Average daily flow of sewage in dry weather	300,000 gallons.		
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Domestic and trade refuse. Surface water included.		
Number of water closets in area drained	Comparatively few. No exact record.		
LAND.			
Total area	11 acres 1 rood 10 perches.		
Whether underdrained, and how?	Not underdrained.		
Nett area upon which sewage can be treated			
TANKS.			
Number and total capacity	Six. 245,000 gallons.		
Used all together, or in series	In two series.		
Whether flow of sewage continuous, or time allowed for settlement	Continuous.		
CHEMICALS.			
Nature	Lime and alumino-ferric.		
Quantity	100 tons of lime of 24 tons of alumino-ferric.		
How added	Milk of lime and afterwards alumino-ferric in block.		
FILTERS.			
Number and total area	Two. 303 square yards.		
Construction	Coke breeze.		
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. Not on Dibdin's method.		
STORM OVERFLOWS.			
Number on line of sewers and at outfall works	Four.		
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Fixed side weirs.		
Proportion of flow in sewer to average flow when storm overflows begin to act	No record.		
COST OF—			
Land	£1,850.

Appendix 4.

WETHERBY RURAL DISTRICT.—SHADWELL INDUSTRIAL SCHOOL SEWAGE WORKS

Date completed and brought into operation	Several years ago.
Engineer	None. We were guided by the advice of Dr. Cameron, Leeds Medical Officer of Health.
Whether sanctioned by L.G.B.	No. We submitted the scheme to the Home Secretary, who is the authority for Industrial Schools.
Area and population or number of houses drained	180 boys and officers and Superintendent's family. Say 200 in all.
Average daily flow of sewage in dry weather	Regret I cannot give this.
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	There are 2 W.C.'s, lavatory, laundry and for the whole Institution, kitchen sinks, &c. No.
Number of water closets in area drained	2.
LAND.	
Total area	20 acres.
Whether underdrained, and how?	Ordinary land drains connected with beck.
Nett area upon which sewage can be treated	Very little land below level of tanks.
TANKS.	
Number and total capacity	2. Large, with ample capacity. Do not know the precise quantity they will hold.
Used altogether, or in series	Alternately.
Whether flow of sewage continuous, or time allowed for settlement	Plenty of time allowed for settlement.
CHEMICALS.	
Nature	Alumino-ferric cake, and at present oxynite being tried.
Quantity	About 30 grains to gallon.
How added	Put into drain before reaching tanks.
FILTERS.	
Number and total area	No filtration. A fairly satisfactory effluent attained.
Construction	Do
Whether used continuously or intermittently, and (if the latter) whether on Dibden's method	Do.
STORM OVERFLOWS.	
Number on line of sewers and outfall works	None.
Construction—whether fixed side wiers, leaping wiers, or adjustible valves	Do.
Proportion of flow in sewer to average flow when storm overflows begin to act	Do.
COST OF—	
Land	We spent about £400 in the drainage and tanks. I am sorry I cannot apportion it.
Laying out of land	
Tanks	
Filters	

	1895.	1896.	1897.
SLUDGE.			
Amount	The tanks are cleaned at intervals, and the sludge carried on the land. There is very little sludge, and the cost is very trifling, as it is only a question of labour for the big boys under detention.		
How dealt with			
Cost, or			
Return			
PRODUCE.			
Crops	No application to this system.		
Value			
WORKING EXPENSES.			
Labour	Only the small cost of chemicals, quite inappreciable.		
Chemicals			
Pumping

YEADON URBAN DISTRICT.—YEADON SEWAGE WORKS.

Date completed and brought into operation	About 1881.
Engineer	McLandsbro & Preston.
Whether sanctioned by L.G.B.	Yes.
Area and population or number of houses drained	
Average daily flow of sewage in dry weather	
Nature of sewage (domestic or mixed with trade refuse). Is surface water included?	Mixed with trade refuse. Yes.
Number of water closets in area drained	
LAND.	
Total area	4 acres 3 roods 3 perches.
Whether underdrained, and how?	No.
Nett area upon which sewage can be treated	
TANKS.	
Number and total capacity	2 storage tanks, 3 settling tanks.
Used all together, or in series	Altogether.
Whether flow of sewage continuous, or time allowed for settlement	Continuous.
CHEMICALS.	
Nature	Lime.
Quantity	16 tons per month
How added	Mixing machine.
FILTERS.	
Number and total area	1 filter. Area 324 square yards. Two more in course of construction, with an area of about 600 square yards.
Construction	Rubble and rough and fine clinkers.
Whether used continuously or intermittently, and (if the latter) whether on Dibdin's method	Intermittently. No.
STORM OVERFLOWS.	
Number on line of sewers and at outfall works	
Construction—whether fixed side weirs, leaping weirs, or adjustable valves	Adjustable valve.
Proportion of flow in sewer to average flow when storm overflows begin to act	
COST OF—	
Land	Leasehold, £74 15s. 0d. per year.
Laying out of land	
Tanks

SUMMARY.

No.	Treatment and Nature of Sewage.	Reports of Inspectors.		Results of Analyses.		Percentage below limit.
		Satisfactory.	Unsatisfactory.	Above limit.	Below limit.	
	Settlement or Chemical Precipitation, followed by Artificial Filtration and Filtration through Land:					
12	(*a*) Domestic sewage only	152	56	7	4	36
3	(*b*) Sewage mixed with trade refuse	16	51	1	3	75
	Artificial Filtration:					
11	(*c*) Rapid (mechanical ?) filter. Domestic sewage only.	38	100	2	3	60
—	(*d*) Rapid (mechanical ?) filtration. Sewage mixed with trade refuse.	—	—	—	—	—
4	(*e*) Biological filtration. Domestic Sewage only.	7	32	1	—	—
1	(*f*) Biological filtration. Sewage mixed with trade refuse.	8	7	—	—	—
	Filtration through Land:					
46	(*g*) Domestic sewage only	414	181	20	5	20
9	(*h*) Sewage mixed with trade refuse	100	100	3	7	70
	Chemical Precipitation or Settlement:					
10	(*i*) Domestic sewage only	24	74	—	3	100
6	(*j*) Sewage mixed with trade refuse	15	148	—	5	100
	Settlement or Chemical Precipitation, followed by Filtration through Land:					
66	(*k*) Domestic sewage only	684	315	16	12	43
20	(*l*) Sewage mixed with trade refuse	176	256	14	23	62
	Settlement or Chemical Precipitation, followed by Artificial Filtration:					
18	(*m*) Domestic sewage only	205	75	13	7	35
12	(*n*) Sewage mixed with trade refuse	100	209	3	30	91

The period to which the statistics refer is from 1st January, 1898, to 30th September, 1899.

The limit of impurity adopted is absorption of one grain per gallon of oxygen at 80° Fahrenheit.

APPENDIX No. 5.

RIBBLE JOINT COMMITTEE.

PARTICULARS as to the methods of Sewage Treatment adopted by Local Authorities in the Ribble Watershed

NOTE.—In judging the quality of Effluents for regular Monthly Reports, samples liberating less than ·1 Albuminoid Ammonia in parts per 100,000 are classed "good" in the absence of other easily-observed for such Ammonia. Others are classed as "fair" or "poor" according to the amount of Albuminoid Ammonia between these figures. In the following Tables the dividing line between good and bad is ·16 part

NAME OF AUTHORITY.	Population.	Number of Houses connected with Sewers.	Average Daily Flow of Sewage (per 24 Hours) in Gallons.	Number of Firms turning Trade Waste into Sewers, and the Character of Same.	Number of Precipitation Tanks and Total Capacity in Gallons.	Precipitants used.	Quantity of Precipitants used per Week.	Number of Artificial Filters and Total Area of Same.
1.	2.	3.	4.	5.	6.	7.	8.	9.

Small portion of sewage only treated on biological filters. 5 acres of biological filters to be put down.
Natural bed of sand (underdrained).	Intermittently, clarified tank effluent, 25 gallons per square yard.	370 acres	50 acres	20 tons. Sold to farmers.	Treated during night	1 3	9 1	10 4	90 25	Earth filter effluents. Irrigation effluents. Portions of sewage from Orrell, Ince, Aspull, and Standish, treated at works.
—	—	20 acres	10 acres	45 tons pressed cake. Given to farmers.	Yes	4 9	— 5	4 14	— 35·5	Tank effluents. Irrigation effluents.
—	—	17 acres	7 acres	Pressed and carted away by farmers.	Day treatment continued for 19 hours.	7	11	18	61·0	Irrigation effluents.
—	—	14 acres	4 acres	Given to farmers	Yes	—	15	15	100	Irrigation effluents. Diluted with extraneous ground water.
—	—	About 2 acres	1 acre	Used as manure on beds.	Yes	5	11	16	68·5	Irrigation effluents (small district).
Total depth 18in., broken stone 6in., sharp sand 3in., coke breeze 9in.	Continuous, domestic sewage, 2,416 gallons.	8 acres, 11 additional acres of land to be added.	—	3½ tons. Farmers cart away.	Yes	2	6	8	75·0	Irrigation effluents.
—	—	3½ acres	—	—	—	—	5	5	100	Irrigation effluents. The tank effluent is filtered through sand and coke filters before passing on to land.
—	—	37 acres, broad irrigation.	33 acres. Used occasionally.	37½ tons (wet). Used on land.	Yes	7	10	17	58·75	Irrigation effluents. All house drains not yet coupled to sewers.
—	—	120 acres	12 acres	About 10 tons (wet). Spread on land.	Yes	4	20	24	83	Irrigation effluents. Diluted with extraneous ground water.
Cinders, 3 ft. 6in. deep	Alternately for final treatment.	30 acres	42 acres	—	Yes, as a general rule.	6	4 9	10 10	40 10	Irrigation effluents. Filter effluents.

Handed in by Mr. F. Scudder, F.C.S., F.I.C.

ANALYSES OF SAMPLES OF SEWAGE EFFLUENTS FROM SANITARY AUTHORITIES IN THE MERSEY AND IRWELL WATERSHED.

Appendix 6.

APPENDIX No. 6.

Table A.

ANALYSES OF SAMPLES OF SEWAGE

No.	Authority.	State of Weather.	Date. 1900.	Time.	Method of Purification.	Remarks on Sample as received.
1	Little Lever U.D.C.	Showery	23 Aug.	2.20 p.m.	Tanks and filters	Clear, colourless. No smell
2	Crompton U.D.C.	Fine	12 Sept.	12 noon	Tank and filter	Clear, colourless. No smell
3	Cheadle and Gatley U.D.C.	Dry	15 Aug.	12.30 p.m.	Tanks and filters	Clear, colourless. No smell
4	Westhoughton U.D.C. (Marsh Brook).	Fine	28 Aug.	11.30 a.m.	Land treatment	Clear, colourless, trace of brown sediment. No smell.
5	Hayfield R.D.C.	Dry	10 Sept.	1.30 p.m.	Tanks and land	Faint brown colour, trace of brown sediment. Very faint smell.
6	Romiley U.D.C.	Dry	13 Sept.	11 a.m.	Bacteria beds	Clear, colourless. No smell
7	Hollingworth U.D.C.	Dry	6 Sept.	2.30 p.m.	Tanks and filters	Faint brown colour, traces of brown sediment. No smell.
8	Littleborough U.D.C.	Fine	10 Sept.	2.15 p.m.	Tanks and filters	Clear, colourless. No smell
9	Ashton - on - Mersey U.D.C.	Dry	29 Aug.	2 p.m.	Tanks and land	Clear, colourless, trace of brown sediment. No smell.
10	Wilmslow U.D.C. (Northern Outfall).	Showery	23 Aug.	10 a.m.	Tanks and land	Slightly turbid, no sediment. Faint soapy
11	Bucklow (Timperley) R.D.C.	Dry	17 Sept.	1 p.m.	Tanks and filters	Slightly turbid, brown sediment. No smell
12	Mossley Corporation	—	20 Sept.	2.50 p.m.	Tanks and filters	Light brown, with brown sediment. Faint earthy smell.
13	Hindley U.D.C. (Hindley Green).	Hot, dry	16 Aug.	3.15 p.m.	Tanks and filters	Clear, trace of sediment. No smell
14	Chapel-le-Frith R.D.C.	Dry	12 Sept.	1 p.m.	Tanks and land	Clear, colourless. No smell
15	Disley R.D.C.	Dry	10 Sept.	4.30 p.m.	Tanks and land	Faintly turbid, no sediment. Soapy smell
16	Abram U.D.C.	Fine	13 Sept.	4.30 p.m.	Bacteria beds	Clear, colourless, traces of sediment. No smell
17	Lymm U.D.C.	Dry	1 Aug.	2.30 p.m.	Tanks and willow beds.	Brown, with brown sediment. No smell
18	Bowdon U.D.C.	Dry	29 Aug.	12.30 p.m.	Tanks and land	Clear, colourless, traces of brown sediment. No smell.
19	Royton U.D.C.	Fine	12 Sept.	11 a.m.	Tanks and filters	Clear, little brown flocculent sediment. No smell.
20	Ashton - in - Makerfield U.D.C.	Hot, dry	16 Aug.	12.45 p.m.	Tanks and land	Clear, trace of granular sediment. No smell
21	Bucklow R.D.C. (Northenden).	Dry	15 Aug.	1.30 p.m.	Tanks and land	Brown colour, brown sediment. Very faint smell.
22	Bolton Corporation (Rhodes Farm).	Fine	4 Sept.	11.45 a.m.	Tanks and land	Clear, colourless, small amount of brown sediment. Very faint earthy smell.
23	Alderley U.D.C.	Showery	23 Aug.	12 noon	Tanks and land	Slightly turbid, traces of sediment. Faint soapy smell.
24	Wilmslow U.D.C. (South Outfall).	Showery	23 Aug.	11 a.m.	Tanks and land	Clear, colourless. No smell
25	Westhoughton U.D.C. (Rogers Farm).	Fine	28 Aug.	1 p.m.	Tanks, filters, land	Clear, brown sediment. No smell
26	Worsley U.D.C. (Boothstown).	Fine	29 Aug.	2.45 p.m.	Tanks and land	Clear, trace of grey sediment. Faint earthy smell.
27	Macclesfield R.D.C. (Poynton).	Dry	5 Sept.	5 p.m.	Tanks and land	Clear, colourless, some grey sediment. Very faint smell.
28	Oldham Corporation	Fine	5 Sept.	11 a.m.	Tanks and filters	Faint turbidity, little grey sediment. Faint smell.
29	Mottram U.D.C.	Dry	6 Sept.	10.30 a.m.	Tanks	Liquid clear, trace of grey sediment. No smell
30	Failsworth U.D.C.	Fine	5 Sept.	1.45 p.m.	Tanks and filters	Faint turbidity, trace of brown sediment. No smell.
31	Altrincham U.D.C.	Dry	17 Sept.	2 p.m.	Tanks and land	Brown, with brown sediment. Slight earthy smell.
32	Hale No. 2 Outlet	Dry	29 Aug.	11 a.m.	Tanks and land	Almost clear, little brown sediment. No smell
33	Stockport R.D.C. (Offerton).	Dry	13 Sept.	1 p.m.	Tanks and filters	Pink colour, trace of sediment. Faint smell
34	Denton U.D.C.	Fine	30 Aug.	1.45 p.m.	Tanks and filters	Almost clear, no sediment. Very faint smell
35	Kearsley U.D.C.	Hot, dry	14 Aug.	1.10 p.m.	Tanks and filters	Fairly clear, traces of grey sediment. No smell
36	Swinton and Pendlebury U.D.C. (Pendlebury).	Fine	4 Sept.	12.45 p.m.	Tanks and filters	Liquid clear, little grey sediment. Slight earthy smell.
37	Urmston and Flixton J.S.B.	Fine	14 Sept.	9.30 a.m.	Tank effluent	Liquid faintly turbid, trace of dirty sediment. Very faint smell.
38	Stockport Corporation	Dry	15 Aug.	10 a.m.	Tanks and land	Faintly turbid, brown sediment. Faint smell
39	Droylsden U.D.C.	Fine	5 Sept.	3 p.m.	Tanks and filters	Faintly turbid, quantity of brown sediment. Faint smell.
40	Marple U.D.C.	Dry	13 Sept.	12 noon	Tanks and filters	Faintly turbid, trace of sediment. Faint smell
41	Haslingden, Rawtenstall and Bacup S.O.B.	Hot	15 Aug.	1.30 p.m.	Tanks and land	Faintly turbid, little fungus sediment. Slight smell developed.
42	Whitefield U.D.C.	Fine	11 Sept.	12 noon	Tanks and land	Faintly turbid, trace of dark sediment. No smell.
43	Prestwich U.D.C.	Fine	4 Sept.	10.40 a.m.	Tanks and filters	Turbid, little grey sediment. Slight sour smell
44	Tyldesley U.D.C.	Fine	29 Aug.	1.45 p.m.	Tanks and filters	Slightly turbid, trace of sediment. Slight sour smell.
45	Oldham Corporation	Fine	5 Sept.	11.10 a.m.	Tank effluent	Turbid, black sediment. Putrescent smell
46	Salford Corporation	Fine	6 Sept.	12.30 p.m.	Tank effluent	Grey, turbid, traces of grey sediment. Alkaline. Lime effluent smell.
47	Salford Corporation	Showery	22 Aug.	3.10 p.m.	Tank effluent	Grey, turbid, dark sediment. Alkaline. Nitrites present. Tarry smell.
48	Hyde Corporation	Fine	30 Aug.	12.45 p.m.	Tank effluent	Grey, turbid. Putrescent smell
49	Farnworth U.D.C.	Hot, dry	24 July	2.15 p.m.	Tank effluent	Slightly turbid, finely divided sediment. Strongly alkaline. Lime effluent smell.
50	Manchester Corporation	Fine	6 Sept.	2 p.m.	Tank effluent	Brown, turbid, with dark sediment. Strong tarry smell.
51	Manchester Corporation	Fine	21 Aug.	1.30 p.m.	Tank effluent	Brown, turbid, brown sediment. Very strong tarry smell.

September, 1900.

Appendix 7.

APPENDIX No. 7.

Handed in by JOHN C. THRESH, Esq., M.D.

REPORT ON AN OUTBREAK OF TYPHOID FEVER AT SHOEBURYNESS ATTRIBUTED TO EATING COCKLES.

By JOHN C. THRESH, M.D., &c., Medical Officer of Health, Essex County Council, and E. R. WALTER, M.R.C.S., Medical Officer of Health, Shoeburyness.

Shoeburyness is an urban district at the extreme south-east of the county of Essex, bounded on the south by the Thames, on the east by the German Ocean, and on the north and west by the Rochford Rural District, of which until recently it formed a part. Nearly the whole of this area has a high death rate from typhoid fever, and every autumn outbreaks of greater or less intensity occur.

The population of Shoebury at the last census was 2,990, but it is now believed to be over 4,000. This does not include the garrison or school of gunnery which is within the district. It is on the London clay, but this is covered, save along the coast, by beds of post-glacial gravel and sand and by brick earth. The abundance of the latter causes brickmaking to flourish, and a considerable portion of the population is employed in the brickfields. The whole area is fairly flat, but it is well above the sea level.

Until about two years ago the town derived its supply of water from shallow wells, most of which were liable to serious pollution. The present supply is from a deep well piercing the London clay, and yielding a supply of great organic purity. The waterworks were designed by Mr. Mansergh, and the works carried out under the supervision of his firm. They appear to me to be very satisfactory, and except in the outlying portions of the district, the population is now supplied from the works. Many wells have recently been closed.

The town is sewered, but certain of the sewers have little fall, and have no automatic flushing arrangement. There are three outfalls on the beach for the crude sewage. The most important one, the eastern outfall, has just been extended seaward 300 yards, but there can be no doubt that with the incoming tide the sewage, highly diluted, is carried over the beach (clay and sand). On this beach cockles (and other shell fish, mussels, and winkles) are found in some abundance. Cockles are collected when the tide is down, by children and others, and it is not unusual for such people to force open the shells and eat the fish in an uncooked condition. They are, however, chiefly taken home and cooked by steaming in a saucepan until the shells are all open. The cockles are placed in a covered saucepan with a little water, and then put over the fire. As soon as the water boils, or even before, the shells open, and this is the sign of their being cooked. It is tolerably certain that this method of cooking does not effect sterilisation.

There are 497 waterclosets connected with the sewers. The scavenging is fairly satisfactory, the few remaining pail closets being emptied three times a week, and the ashbins weekly. There is a certain amount of overcrowding. This is decreasing on account of recent building operations, but house rental is high, and many recently erected houses contain two families. There is no isolation hospital. An arrangement has been made to send patients to the Rochford Rural District Hospital when that is completed.

In the brickfields a great deal of house refuse (soft core) from London is used. This is brought by barges and chiefly used in brick burning. The burning causes an effluvium nuisance the prevention of which has occupied much of the attention of the District Council, but it has not as yet been found possible to take any steps to prevent the nuisance without injuriously affecting the industry upon which so much of the prosperity of the town depends.

7	No. 10	F., 3, October 24th.	

Out of the 10 houses, 7 have been infected, and there have been 23 persons attacked.

In the early part of the present year there had been few cases of typhoid fever; 1 in April, 2 in May, and 1 in June. There was a five weeks' interval between the last case in May and the one in June. This latter case the medical officer of health suspected to be due to eating cockles picked up from the beach. On July 10th a case was notified from a terrace of ten houses, only completed about two years ago, and in which the inspector could find no sanitary defects. The cases which occurred in this terrace are tabulated in column 1.

In the remainder of Shoebury there have only been eleven cases since July 1st. When the unusual incidence of fever in this group of houses was obvious, a sample of water from the main supplying the terrace, and samples of milk from each of the four dealers supplying the families residing there, were taken and examined chemically and bacteriologically in the County Public Health Laboratory.

The water was found in all respects satisfactory. Neither the bacillus coli nor bacillus enteritidis was discovered. Three of the samples of milk were of good average quality, and contained neither of the above organisms. The fourth was evidently mixed with water, and contained both organisms. This milk was being supplied to two houses only. It was being used in other parts of the town, but in no other house so supplied was there any case of fever. Although "fouled" there was no reason to suspect it as being the cause of the outbreak. In fact, neither milk nor water can be reasonably suspected as the cause of the outbreak. Not a single fact has come to light appearing to implicate either.

The houses are of very recent erection, and stand upon an estate which has been divided up into building plots. It was previously a meadow, so that the subsoil cannot be polluted. In construction they conform to all the model building bye-laws, and they appear to be in a very good sanitary condition. Each house drains separately into a sewer which runs behind, and is cut off from the sewer by a Weaver trap. This sewer, or combined drain, is also trapped off from the main sewer, which runs in front of the houses. Each house has a water closet upstairs and one in the yard, and the soil pipe is carried up in each house full bore and straight, to a few feet above the eaves. No smell has ever been observed from any of the soil pipes. The drains and soil pipes have been tested with smoke, and no defects were discovered. The sink pipes are properly disconnected and the yard paved. The closets have flushing cisterns, and appear in good order.

Two of the earlier cases of typhoid fever which occurred prior to the outbreak in the terrace were in houses connected with this sewer at points above the terrace, and the sewer has little fall. It would doubtless therefore become infected, and infected material could lodge in it, but it is difficult to see how this could affect the terrace. There is no reason to suspect any defects in the sewer or water main whereby one could affect the other.

Just above the terrace on the opposite side of the road is a kind of farmyard in which manure is stored, and some time ago some very offensive material was stored here. It was not deposited there until after fever had appeared, and as soon as complaints were made it was covered over, and the nuisance abated. This, therefore, can be excluded as the cause.

Most of the cottages were tenanted by persons working in the brickfields, and it was possible that they might have handled and been infected by the soft core used. Against this is the fact that only two of the persons attacked handled this material, and that no other case occurred amongst the very many who were constantly in contact with it. Could the effluvium from the brickfields carry contagion? Such an occurrence has not been recorded, and there are many houses nearer the brickfields than this terrace, and these houses have not suffered to nearly the same extent.

The two end houses of the terrace are occupied by persons in a much better position than those in the other houses. All the inhabitants of No. 1 have so far escaped. At the opposite end, No. 10, a girl, aged three, has just been attacked. Here, however, there is a possible cause. After fever had begun to spread it was decided to improve the ventilation of the main

sewer by running a tall shaft up the side of this house. When this was being done the tenant says there was a vile smell, which penetrated into the house. The date could not be fixed, but it was apparently between fourteen and twenty-one days prior to the child first appearing to be ill.

With the exception of the case last notified, all the usual cases of typhoid fever would appear to have had no part in producing the outbreak. There remains only for consideration the question of infected food. There is but one article likely to carry infection which has been eaten so largely or by so many of the sufferers as to merit serious attention. It has already been stated that the large expanse of foreshore is liable to sewage pollution, and that on this foreshore, lying upon and in the superficial layer of mud, cockles are comparatively abundant, and that these cockles are gathered by children and others, and are sometimes eaten uncooked. Samples of these cockles were collected by the sanitary inspector and submitted to examination. There were two lots, one gathered on the beach near the town, and the others further out nearer the sewer outfall. Three examinations were made of each batch (*a*) of the mud adhering to the shells, (*b*) of the fluid inside the shells, and (*c*) of the pulped body of the cockle. The results showed in every instance the presence of the bacillus coli communis, and of the spores of bacillus enteritidis sporogenes. There can be no doubt that all were sewage contaminated.

That the sewage of the town had been specifically infected for some time prior to the outbreak is undoubted, and it does not seem improbable, therefore, that shellfish bathed in such sewage, though diluted with sea water, may become specifically infected, and cause typhoid fever in susceptible people consuming them in an uncooked or imperfectly-cooked condition.

Dr. Walter, in cases which occurred in previous years and in two cases which occurred in the district this year prior to the cases in the terrace, had suspected cockles as the probable cause. One of these cases was notified on June 30th, a child, aged four, living in Wakering Road. No other cause could be assigned, and it was known that the child was in the habit of picking and eating cockles from the beach. The next case which occurred was in the terrace, and this was followed by one in West Road. In both these the eating of cockles appeared the most probable cause. Such being the case, careful inquiries were made at all the houses in the terrace, with the following results taken in order of invasion:—

"House No. 8. Four cases occurred here; the dates of notification show that some of the later ones were probably secondary, but they may have been due to the same cause as the first. Children often on the beach gathering cockles. Those brought home were cooked before being eaten. The family has since removed, and we could not get further details.

"House No. 9. Seven cases occurred in this house. The first notified was a girl, aged 13. The parents at first asserted that they rarely ate cockles, and that none had entered the house since May, and the child did not remember having had any. Afterwards the family acknowledged that all except the father often had cockles, and that the children were constantly on the beach during the summer months gathering them. They certainly had cockles on more than one occasion early in August, the last occasion being on or about August 9th, two days after Bank Holiday. This would account for the earlier cases, and the others were either secondary or caused by the children eating cockles as they picked them from the beach. The father denies ever touching shellfish.

"House No. 6. Two cases occurred here, the later one probably being secondary. The patient was a child, aged seven years. The six people in this house ate lots of cockles. They occasionally buy them, but more often pick them from the beach, and wash and boil them before eating. They know that they had some about a week before the child was taken ill.

"House No. 4. Of the eight people in this house, five contracted typhoid fever. Dr. Walter thinks that four of the five were primary cases, the fifth only being secondary. The family admit nearly living upon cockles picked from the beach, boiling them before use. In this house every person was attacked, save a baby aged four months, and a lodger and her child. The lodger and child never touched shellfish, and the baby was obviously too young to eat cockles.

"House No. 5. Of the three occupants of this house two had typhoid fever, and both were attacked at the same time, and notified September 15th. They only rarely partook of shellfish, but early in August (Bank Holiday) they had some oysters, and near the end of the month they had some cockles collected from the beach. These they cooked. This would be about the time when they become infected.

Appendix 7.

"House No. 7. Of the six persons in this house two contracted fever. One, a lodger, as soon as he felt ill went off home. The other was an adult, notified on September 16th, at which time the lodger was found to be ailing. This family rarely took shellfish, but about three weeks before the attack the people next door gave them a plate of boiled cockles. The people who gave them the cockles have since left. They only occupied the adjoining house for a few weeks and then removed.

"House No. 10. The last case notified in the terrace. One of the end houses occupied by a man in fairly good position. Patient a child aged three. The mother says that none of the children have ever tasted cockles, and she would not have such things in the house. The nuisance caused by erecting the ventilating shaft at the side of this house has already been referred to. Of the remaining three houses unattacked No. 1 (end house) the family had partaken of cockles several times during the summer. They did not pick them, but purchased them at the door. The other two houses are now unoccupied, and appear only to have been occupied occasionally, and for a few weeks at a time, since their completion."

The subjoined table shows that in the terrace referred to a larger proportion of males than females were attacked, that children suffered more, proportionally, than adults, and that about one-third of the occupants have had typhoid fever. Only three cases proved fatal. As the result of an inquiry we are strongly inclined to the opinion that this outbreak was due to the eating of cockles, and our reasons may be briefly summarised as under:—

Age and Sex of Occupants of Nine Occupied Houses in the Terrace.

——	Under 5.	Under 10.	Under 15.	Under 20.	Under 25.	Under 35.	Under 45.	Under 55.	Total.
Males.									
Attacked with typhoid fever	4	2	2	1	1	2	1	–	13
Not attacked	4	2	3	1	4	2	2	1	19
Females.									
Attacked with typhoid fever	2	3	1	2	–	2	–	–	10
Not attacked	3	3	3	2	4	3	5	–	23
Males and Females.									
Attacked with typhoid fever	6	5	3	3	1	4	1	–	23
Not attacked	7	5	6	3	8	5	7	1	42

1. There is no evidence tending to implicate the water supply.

2. There is no evidence tending to implicate the milk supply. It is true that one supply was impure, but it was only used in two out of the seven houses infected. The houses were supplied with milk from four different sources, and nothing occurred in any other part of the town to implicate any of the sources from which milk was obtained.

3. The drainage arrangements were unusually good.

4. The subsoil was free from polluting matter.

5. Cockles were eaten by nearly all the persons attacked, and these cockles were obtained from a source known to be polluted by sewage. Moreover, cockles gathered from this source showed when examined bacteriologically unmistakable signs of sewage pollution.

6. Cockles from the beach are consumed chiefly by newcomers to the district. The men in the garrison are expressly forbidden to eat any shellfish from the beach, and the older residents regard them with suspicion, it being well known that typhoid fever has been attributed to eating them. The residents in the infected houses were all recent arrivals in the town.

Appendix 8.

APPENDIX No. 8.

LETTER from SIDNEY BARWISE, Esq., M.D. (Lond.), D.P.H. (Camb.), and a REPORT on the PURIFICATION of SEWAGE at the BURTON SEWAGE FARM.

County Offices,
St. Mary's Gate,
Derby.

July 29, 1901.

Dear Sir,—With reference to the evidence I gave before the Royal Commission on Sewage Disposal on the purification of the Burton sewage at the Burton Farm, I should be glad if you would lay the enclosed report before the Commission.

Since I gave my evidence I have had an opportunity of trying the effect of a biological filter worked continuously with intermissions upon the Burton sewage, after precipitation with lime.

Briefly, the conclusions arrived at are:—

1. That the excessive amount of lime (the tank effluent containing as much as 8 grains of free lime to the gallon) is harmful.

2. That when the excess of lime is neutralised an excellent effluent can be produced by means of filtration when the filter is worked at the rate of half a million gallons per acre per day.

The results of daily analyses throughout 12 months are contained in the appendix to this report.

This table gives the organic ammonia in the tank effluent, and in the filtrate, the nitrogen as nitrates, the alkalinity of the tank effluent, the temperatures, and the rainfall.

If necessary, I will make an affidavit that the report is correct, or if preferred I will swear to it any time the Commission is sitting.

I am,
Your obedient servant,
SIDNEY BARWISE.

The Secretary of the Royal Commission on Sewage Disposal, 39, Victoria Street, Westminster, S.W.

To the Chairman and Members of the Public Health Committee of the Derbyshire County Council.

My Lord and Gentlemen,—As mentioned in the memorandum of an interview betwen Professor Dewar and myself, dated January 31st, 1899, subject to the approval, subsequently given, of your committee and the Corporation of Burton, it was agreed:—

i. That an experimental biological filter should be constructed and reported on by me.

ii. That a certain area of the farm should be set aside and used only for the deposition of sludge, and an adjoining area of land should be irrigated with clarified sewage only.

The experiments have now been in progress for twelve months, and the results obtained are of such an important character, that, for the information of your committee and the advisers of the Corporation, I have prepared an epitome of these results and the conclusions to be drawn therefrom.

It is, perhaps, worth while recalling that I had reported to your committee that the unsatisfactory character of the effluent from the Burton farm was, in my opinion, in part due to the deposit of carbonate of lime forming an impervious layer over the surface of the soil, thereby preventing the ready access of air into its interstices. It was also in my opinion partly due to the excess of lime acting detrimentally on the nitrifying organisms in the surface layers of the soil. To test these opinions, on a certain area of the farm known as Plot 16, the sludge has all been deposited in two trenches before the sewage is applied to the land.

PLOT 16.—The following are the result of analysis of the effluent from Plot 16, and in parallel columns the results of the analysis of the general effluent from the farm:—

Date.	Parts per 100,000.			
	Farm Effluent.		Effluent Plot 16.	
	Organic Ammonia.	Nitrogen as Nitrates.	Organic Ammonia.	Nitrogen as Nitrates.
17 Mar. 1900 -	—	—	·06	·35
23 Mar. ,, -	—	—	·05	·5
24 Mar. ,, -	·21	nil	—	—
31 Mar. ,, -	—	—	·05	—
18 May ,, -	·15	nil	·08	·3
22 May ,, -	·18	nil	—	—
26 May ,, -	—	—	·07	·4
2 June ,, -	—	—	·01	·03
14 June ,, -	·17	nil	·09	nil
23 June ,, -	—	—	·08	—
			Plot 16 rested from 23rd June to 1st September.	
1 Sept. ,, -	—	—	·12	—
7 Sept. ,, -	—	—	·05	·45
15 Sept. ,, -	·13	nil	·06	·35

It is impossible to say to what extent the alkalinity of the sewage applied to Plot 16 was neutralised by its running through the open carriers, but at any rate no suspended carbonate of lime was carried over on to the land so as to seal its surface. Plot 16 has an area of 17 acres, about 7 acres of which were irrigated on alternate days, so that the same area came into use every fifth or sixth day, while the rest of the farm, in use for the time being, is irrigated for a month or two on alternate days and then allowed to rest. The results obtained on Plot 16 are satisfactory. Nitrates are present to the extent of from ·3 to ·5 parts per 100,000. Assuming that Plot 16 was irrigated at the same rate as the rest of the farm, 30,000 gallons of sewage were applied per acre per day; but taking into consideration that only 7 out of the 17 acres were irrigated each day, it is more likely that only half this amount was applied to the land. When we remember that Plot 16, to give these results, needs prolonged rests of several months, it will be apparent that a large increase of the farm would be necessary if the whole of the sewage was to be treated on the same lines.

The suggestion is therefore made that certain areas of the farm should be levelled, and used as intermittent filters, to enable a larger quantity of sewage to be applied, while the rest of the farm is used for irrigation on the lines of Plot 16.

RESULTS OBTAINED BY BIOLOGICAL FILTRATION.

The experiments with the biological filter have consisted of:—

1.—Applying the clarified limed sewage after it has passed through a settling tank.

2.—Neutralising the excess of lime and applying the neutralised sewage to the filter.

3.—Allowing the sewage applied to the filter to gradually become alkaline again, the quantity of nitrates formed under the varying conditions being carefully noted.

The results obtained are set forth in the appendix to this Report.

It will be noticed that, although there was a large reduction in the organic ammonia immediately the coal filter was started, yet no nitrates were produced. This was to me a new experience with filters of this kind, and in November of last year I had the filter carefully seeded from an experimental filter at work at Buxton, which is actively nitrifying. This, however, had no result; the sewage was then being applied during 12 hours, the filter having a rest for 12 hours each night, the rate of filtration was 1,000,000 gallons per acre per day; the rate of filtration was reduced to half this quantity, and, although a reduction in the organic ammonia resulted, no nitrification took place. In December the quantity was further reduced to the rate of a quarter of a million gallons per acre per day, the sewage being applied intermittently every half hour, the filter also resting 12 hours during the night. This reduction did not induce nitrification, although it further reduced the organic matter in the filtrate. Accordingly in December I attempted to cause a reduction in the alkalinity by having part of the settling tanks made into an anaerobic bacteria bed by filling it with coarse gravel and letting the sewage travel through it laterally. I had hoped that some organisms would develop, which would give off carbonic acid and thereby neutralise the lime, but this did not happen. I noticed, too, that the surface of the coal filter was becoming caked and hard. The filter had now been at work nearly six months and no nitrates had appeared. I therefore obtained permission to neutralise the excess of lime by means of copperas. Although this was an extravagant way of doing it, for the purpose of the experiment, it was easily applied.

As the lime had, in my opinion, killed the nitrifying organisms which had been added to the filter, it was again seeded from actively nitrifying biological filters, and so that the conditions for nitrification should be as favourable as possible, the quantity applied was temporarily reduced to the rate of one hundred and twenty-five thousand gallons per acre per day. Nitrates soon made their appearance, and the rate of filtration was gradually increased to the rate of half a million gallons per acre per day, at which rate while the sewage was neutral or nearly so, an excellent effluent was produced, containing less than ·05 parts per hundred thousand of organic ammonia and more than one part of nitrogen in the completely oxidised form of nitrates.

I might, perhaps, here point out that while the tank effluent contained free lime to the extent of about eight grains per gallon, no sign of any kind of animal or vegetable life could be seen in the tanks, or the carrier conveying the tank effluent to the filters. The sewage showed no growth on gelatine plates, it was not only practically sterile, but killed worms and frogs if they happened to fall in. As soon, however, as the sewage was neutralised, various forms of animal and vegetable life could be seen in the tanks, and the carrier to the filter became coated with iron bacteria. The tank effluent now most readily oxidised into nitrates, and the filtrate from the filters contained numbers of the Tubifex Rivulorum, a perfectly harmless non-parasitic water organism.

The following table of analyses by the county analyst shows the condition of affairs at this time:—

Date of Collection, June 14th, 1900.

	Results expressed in parts per 100,000.				
	Limed Sewage.	Tank Effluent	Coal Filtrate.	Farm Effluent.	Effluent from Plot 16.
Total Solid Matter	198·0	165·0	146·0	169·0	137·0
Total Suspended Matter	0·0	0·0	0·0	4·8	4·0
Free Ammonia	0·927	1·240	0·015	0·390	0·120
Albuminoid Ammonia	0·620	0·380	0·045	0·160	0·080
Nitrogen as Nitrates	0·0	0·0	1·10	0·0	0·0
Chlorine	11·0	10·2	10·3	10·5	10·7
Oxygen, absorbed in 4 hours at 80 deg. Fahr.	5·566	3·432	0·246	1·700	0·900
Alkalinity as Lime (CaO).	10·64	1·12	0·0	0·0	0·0

An attempt was now made to work the filter at the rate of a million gallons per acre per day; unfortunately for the experiment, the sewage was very highly limed at the time, so that after the copperas had been added there was still four or five parts of free lime in it; the result was that the nitrates began to diminish. By reducing the rate of filtration, however, and adding more copperas, they were again increased to over one part per hundred thousand.

By August all the copperas had gone, and since then the lime has gradually increased up to eight parts per hundred thousand, and the nitrogen as nitrates is gradually diminishing. The filter is being worked at the rate of half-a-million gallons per acre per day.

The following table shows the alkalinity as lime and carbonate of lime in the limed sewage, farm effluent, effluent from Plot 16 and the coal filtrate:—

		Parts per 100,000.	
		CaO.	$CaCO_3$.
Limed Sewage	In suspension	3	40
	In solution	10	30
Farm Effluent		—	45
Effluent from Plot 16		—	32
Effluent from Coal Filter		—	20

The diminishing alkalinity as carbonate of lime is due to the formation of nitric and organic acids as a result of the oxidation of the organic matter in the sewage. The figures show the highly oxidised state of the effluent from the coal filter.

Conclusions:—

The conclusions which I think are to be drawn from these experiments are:—

i. That by a system of biological filtration combined with some modification of the present method of precipitation, a perfectly satisfactory effluent can be obtained, the filters being worked at the rate of half-a-million gallons per acre per day.

ii. That the excessive alkalinity of the sewage is harmful, killing the organisms in the surface layers of the soil, and thus preventing the effluent storing up oxygen by the aid of nitrifying and other oxidizing organisms.

iii. That the deposit of sludge on the surface of the farm is harmful.

Recommendations:—

As a result of the experience obtained, the question should be put to Professor Dewar whether he cannot advise the Corporation to modify the method of precipitation without risk of creating an aereal nuisance. The suggestions I would make are:—

i. That a smaller dose of lime should be added, and, after precipitation has taken place, a small dose of ferric sulphate or such other salt as Professor Dewar may advise.

ii. That rough biological filters or contact beds be constructed of clinker or other hard material, in such positions that the effluent from the filters can be irrigated over the land.

These filters need not cost anything like the same amount as the experimental filter, as since it was designed, various arrangements have been perfected for making bacteria beds practically automatic in their working.

iii. That the system tried with Plot 16 be further extended, so that where irrigation is adopted it is carried out as on Plot 16; it would, however, be better if the sewage were applied for much shorter periods than twenty-four hours.

To permit of this system being adopted with the present area of land, it will be necessary that part of the farm should be made capable of purifying the sewage at a much greater rate. For this purpose it is advisable that at least fifty acres should be properly laid out in carefully levelled horizontal beds (of about a quarter of an acre in extent) of ridges and furrows each about four feet wide, to be used as intermittent land filters; the sewage being applied in a similar manner to that in which it is to the intermittent land filters at Stratford-on-Avon. Here the sewage is applied for half-an-hour at a time, the land then has a rest for one hour, the sewage only being applied for four hours out of the twenty-four, and after five days the portion of the filter used has a rest for several weeks. Under this system four or five times the quantity of sewage can be purified on a given area.

On such a large scale as the Burton Farm it might be said there would be difficulty in working a large number of land filters with sufficient system, but by means of Mather and Platts' automatic sewage distributors or other mechanical appliances the proper intermittent application of the sewage to the land filters can be rendered quite automatic.

In making these recommendations for the consideration of Professor Dewar, I have endeavoured as far as possible to suggest nothing which can be regarded now as of an experimental nature, or anything opposed to the present method of treatment. I do not, therefore, wish it to be understood that these suggestions are the last word which can be said upon the question of the purification of the Burton sewage. It would be remiss on my part if I did not here gratefully acknowledge the great assistance the Sewage Committee of the Corporation of Burton have given me in watching the various experiments, and the kind help I have received from Mr. Lynam and the other officials of the Corporation I have been brought in contact with.

I am, my Lord and Gentlemen,

Your obedient Servant,

Sidney Barwise.

Derby, October 8th, 1900.

Appendix 8.

APPENDIX TO THE REPORT ON THE BURTON SEWAGE FARM.

RESULTS OBTAINED WITH EXPERIMENTAL BACTERIAL FILTER

Appendix 9

APPENDIX No. 9.

A. Circular Letter to Sanitary Authorities in England and Wales enquiring whether they had conducted any experiments on the purification of sewage.

B. A copy of each form mentioned in the Circular Letter.

C. A selection from the Returns made by Authorities on the forms supplied.

Appendix 9A

APPENDIX No. 9A.

ROYAL COMMISSION ON SEWAGE DISPOSAL,
39, Victoria Street, S.W.,
December, 1900.

Sir,

I am directed by the Royal Commission on Sewage Disposal to enquire whether the Council have conducted any experiments as to the purification of sewage by any of the following or similar methods :—

A. Closed Septic Tank and Contact Beds.
B. Open Septic Tank and Contact Beds.
C. *Subsidence Tanks and Contact Beds after chemical precipitation.
D. Subsidence Tanks and Contact Beds.
E. Contact Beds.
F. Closed Septic Tanks followed by continuous filtration.
G. Open Septic Tank followed by continuous filtration.
H. Chemical precipitation, subsidence Tanks and continuous filtration.
K. Subsidence Tanks followed by continuous filtration.
M. Continuous filtration.

* The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

If so, I am to state that the Commission would be much obliged if the Council would kindly furnish them with the results of such experiments.

Forms have been prepared in regard to each of the above mentioned methods, lettered A, B, C, &c., shewing what results the Commission are anxious to see, and it will be of considerable convenience to the Commission to have the results submitted on these forms.

On learning what experiments have been conducted, I shall be happy to furnish you with suitable forms.

I am, Sir,
Your obedient Servant,
F. J. WILLIS,
Secretary.

Estimated or measured dry weather flow of sewage - gallons per day

Is any trade refuse taken into the sewers? - - - -

If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse :

Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers? - - -

Officer under whom the experiment has been conducted

Name and qualification of chemist who has made the analyses - - - - - - - -

---

(1) (*a*) What is the capacity in gallons of the closed septic tank or tanks? - - - - - -

(*b*) If there was more than one tank, state whether they were worked in series or in parallel -

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? - - -

If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion - - - - - - - -

(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material? - -

(*b*) What was the depth of these beds? - - -

(*c*) What were the nature and size of the filtering material? - - - - - - -

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not -

(5) What was the water-holding capacity of the coarse beds at end of experiment? was this measurement made after resting, and, if so, what was the duration of the resting? - - - - - -

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material? - -

(*b*) What was the depth of these beds? - - -

(*c*) What were the nature and size of the filtering material? - - - - - - - -

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not - - - - - - - -

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment? - - - - -

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting? -

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting - - - - - - -

(10) State by what method the tank liquor was distributed on the beds - - - - - - -

Appendix 9B.

(11) What was the average quantity of sewage in gallons dealt with daily? - - - - - - - -

(12) Was the quantity of sewage dealt with increased in time of storm? - - - - - - -

If so, state to what extent, and how the results were affected by such increase - - - - - -

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed - - - - - - -

(14) Give (*a*) the average of the analyses of the final effluent from the beds - - - - - -

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken - - - - -

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed - - - - - -

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible? - - - - - -

(15) Give a typical analysis of the crude sewage to which the experiment relates - - - - - -

(16) Between what dates was the experiment conducted?

If there were any periods of rest, state their duration - - - - - - - - -

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths - - - - -

(18) Was any nuisance caused by the experimental works? - - - - - - - - -

(19) Is the experiment still proceeding? - - - -

If so, may the Commission inspect the works, should they deem it desirable to do so? - -

(20) Give particulars of any other observations of importance which were recorded - - - -

(21) What inferences have been drawn from the experiment? - - - - - - - - -

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system —excluding the annual repayment of any loan - - - - - - - -

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen;

Signature of officer under whose direction the experiment was conducted.

Appendix 9B.

Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Name of authority - - - - - - - -	
Population of district - - - - - - -	gallons per day.
Water supply per head of the population - - -	gallons per day.
Estimated or measured dry weather flow of sewage - -	
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers? - - -	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses - - - - - - - -	

(1) What was the nature of the chemical or chemicals used? - - - - - - - - -	
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used? - - -	
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations - - - - - - -	
(4) What is the capacity in gallons of the subsidence tanks? - - - - - - - - -	
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed- - - - - -	
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent -	
(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(*b*) What was the depth of these beds? - - -	
(*c*) What were the nature and size of the filtering material? - - - - - - -	
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not - - - - - - - - - -	
(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting - - - -	
(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material? - -	
(*b*) What was the depth of these beds? - - -	
(*c*) What were the nature and size of the filtering material? - - - - - - - -	
(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not- - - - - -	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting - -	

Appendix 9P.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting - - - - - - - - -

(13) State by what method the settled sewage was distributed on the beds - - - - - - -

(14) What was the average quantity of sewage in gallons dealt with daily? - - - - - - - -

(15) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase - - - - - -

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed - - - - - - -

(17) Give (*a*) the average of the analyses of the final effluent from the beds - - - - - -

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken - - - - - -

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed- - - - - - -

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible? - - - - - - - -

(18) Give a typical analysis of the crude sewage to which the experiment relates - - - - - -

(19) Between what dates was the experiment conducted? If there were any periods of rest, state their duration

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths- - - - - - - -

(21) Was any nuisance caused by the experimental works? - - - - - - - - - -

(22) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so? - - - - -

(23) Give particulars of any other observations of importance which were recorded - - - - -

(24) What inferences have been drawn from the experiment? - - - - - - - - -

(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or n "Septic" action is produced.

Signature of officer under whose direction the experiment was conducted.

Appendix 9B.

Form D.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS.

Name of authority - - - - - - - -	
Population of district - - - - - -	
Water supply per head of the population - - - -	
Estimated or measured dry weather flow of sewage -	
Is any trade refuse taken into the sewers? If so, state from what processses it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers? - - -	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses - - - - - - -

Form F.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CLOSED SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	
Population of district - - - - - - -	
Water supply per head of the population - - -	gallons per day.
Estimated or measured dry weather flow of sewage -	gallons per day.
Is any trade refuse taken into the sewers?	
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse -	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers - - -	
Officer under whom the experiment has been conducted -	
Name and qualification of chemist who has made the analyses - - - - - - - -	
(1) (*a*) What is the capacity in gallons of the closed septic tank or tanks? - - - - -	
(*b*) If there was more than one tank state whether they were worked in series or in parallel -	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? - - -	
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion - - - - - - - -	
(3) (*a*) What are the form, the area and depth of the filters? - - - - - - - -	
(*b*) State the nature and size of the filtering material -	
(*c*) Were the sides of the filters open or closed? -	
(4) What was the rate of filtration in gallons per square yard per 24 hours?	
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent -	
(5) What was the average quantity of sewage in gallons dealt with daily? - - - - - - - -	
(6) Was the quantity of sewage dealt with increased in time of storm?	
If so, state to what extent, and how the results were affected by such increase - - - - - -	
(7) State by what method the tank liquor was distributed on the filters - - - - - - - - -	
(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed - - - - -	
(9) Give (*a*) the average of the analyses of the final effluent from the filters - - - - - -	
(*b*) the best analysis and date when sample was taken, and	
(*c*) the worst analyses and date when sample was taken - - - - - - - - -	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters - - - - - - - -	
(*e*) the average of the estimations made of the solids in suspension in the final effluent Were these solids putrescible? - - - - - -	

Appendix 9B.

(10) Give a typical analysis of the crude sewage to which the experiment relates - - - -

(11) Between what dates was the experiment conducted?

If there were any periods of rest, state their duration - - - - - - - -

(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths - - - - - - -

(13) Was any nuisance caused by the experimental works? - - - - - - - - -

(14) Is the experiment still proceeding?

If so, may the Commission inspect the works, should they deem it desirable to do so? - -

(15) Give particulars of any other observations of importance which have been recorded - - -

(16) What inferences have been drawn from the experiment? - - - - - - - -

(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—

(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan -

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Form G.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	
Population of district - - - - - - -	
Water supply per head of the population - - -	gallons per day.
Estimated or measured dry weather flow of sewage -	gallons per day.
Is any trade refuse taken into the sewers?	
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse - - - - - - - - -	
Is the storm, soil or surface water, wholly or partially excluded from the ordinary sewers - - -	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses - - - - - - - -	

(1) (a) What is the capacity in gallons of the open septic tank or tanks?	
(b) If there was more than one tank state whether they were worked in series or in parallel -	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? - - -	
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion - - - - - - - -	
(3) (a) What are the form, the area and depth of the filters? - - - - - - - -	
(b) State the nature and size of the filtering material	
(c) Were the sides of the filters open or closed? -	
(4) What was the rate of filtration in gallons per square yard per 24 hours?	
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent -	
(5) What was the average quantity of sewage in gallons dealt with daily? - - - - - - -	
(6) Was the quantity of sewage dealt with increased in time of storm?	
If so, state to what extent, and how the results were affected by such increase - - - -	
(7) State by what method the tank liquor was distributed on the filters - - - - - -	
(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed - - - -	

Appendix 9B.

(9) Give (*a*) the average of the analyses of the final effluent from the filters - - - - - -	
(*b*) the best analysis and date when sample was taken, and	
(*c*) the worst analysis and date when sample was taken - - - - - - - -	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters - - - - -	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible ? - - -	
(10) Give a typical analysis of the crude sewage to which the experiment relates - - - - - -	
(11) Between what dates was the experiment conducted ? If there were any periods of rest, state their duration - - - - - - - - -	
(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths - - - - - - -	
(13) Was any nuisance caused by the experimental works ? - - - - - - - - -	
(14) Is the experiment still proceeding ? If so, may the Commission inspect the works, should they deem it desirable to do so ? - - - -	
(15) Give particulars of any other observations of importance which have been recorded - - -	
(16) What inferences have been drawn from the experiment ? - - - - - - - - -	
(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan -	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9B.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	
Population of district - - - - - - -	
Water supply per head of the population - - -	gallons per day.
Estimated or measured dry weather flow of sewage -	gallons per day.
Is any trade refuse taken into the sewers?	
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers? - - - -	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses - - - - - - - -	

(1) What was the nature of the chemical or chemicals used? - - - - - - - -	
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used? - - -	
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations - - - - - - -	
(4) What is the capacity in gallons of the subsidence tanks? - - - - - - - - -	
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed - - - - - -	
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent	
(7) (*a*) What are the form, the area and depth of the filters? - - - - - - - -	
(*b*) State the nature and size of the filtering material	
(*c*) Were the sides of the filters open or closed? -	
(8) What was the rate of filtration in gallons per square yard per 24 hours? - - - - - -	
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent? -	
(9) What was the average quantity of sewage in gallons dealt with daily? - - - - - - - -	
(10) Was the quantity of sewage dealt with increased in time of storm? - - - - - - - -	
If so, state to what extent, and how the results were affected by such increase - - - - -	
(11) State by what method the tank liquor was distributed on the filters - - - - - - -	

Appendix 9B

(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed - - - - - -

(13) Give (*a*) the average of the analyses of the final effluent from the filters - - - - - -

(*b*) the best analysis and date when sample was taken, and - - - - - - - -

(*c*) the worst analysis and date when sample was taken - - - - - - - - -

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters - - - - - - -

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible? - - - - - -

(14) Give a typical analysis of the crude sewage to which the experiment relates - - - - - -

(15) Between what dates was the experiment conducted? If there were any periods of rest, state their duration

(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths - - - - - - - - -

Signature of officer under whose direction the experiment was conducted.

Appendix 9C.

Form A.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CLOSED SEPTIC TANK AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority	Batley Corporation.
Population of district	1,050 connected with this treatment.
Water supply per head of the population	For domestic purposes 12 gallons per day. For trade purposes 26 gallons per day.
Measured dry weather flow of sewage	15,000 gallons per day.
Is any trade refuse taken into the sewers?	Not into these sewers.
If so, state from what processes it is derived and, approximately, what percentage of the total dry-weather flow of sewage is made up of trade refuse	*Note.* This is an outlying district from which the sewage could not be taken to the outfall works without tunneling through a rocky hill.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted	Oscar J. Kirby.
Name and qualification of chemist who has made the analyses	None made.
(1) (*a*) What is the capacity in gallons of the closed septic tank or tanks?	4,500 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	There are three tanks at different levels, consequently are worked independently of each other.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	These tanks have been working since August 1897 and have not yet had any sludge taken from them.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	*Note.* These beds are improvised by simply digging trenches in the fields and filling them up with coke. They fill during the day and empty during the night. Single contact of course.
(*b*) What was the depth of these beds?	2 feet average.
(*c*) What were the nature and size of the filtering material?	Coke broken to 2 inch cubes.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not	
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	

Appendix 9C.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	See 3a.
(10) State by what method the tank liquor was distributed on the beds.	By an ordinary pipe.
(11) What was the average quantity of sewage in gallons dealt with daily?	15,000 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm?	A little.
If so, state to what extent, and how the results were affected by such increase.	No appreciable difference.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	None made.
(14) Give (*a*) the average of the analyses of the final effluent from the beds.	
(*b*) the best analysis of the final effluent and date when sample was taken, and	
(*c*) the worst analysis of the final effluent and date when sample was taken.	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(15) Give a typical analysis of the crude sewage to which the experiment relates.	
(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	None whatever.
(19) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes, certainly.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	The following, viz.:—That for comparatively small quantities of domestic sewage the method described is a cheap and efficient one.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

O. J. KIRBY.
Signature of officer under whose direction the experiment was conducted.

Form A.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CLOSED SEPTIC TANK AND CONTACT BEDS.

Name of authority	Manchester.
Population of district	550,000 gallons.
Water supply per head of the population	Domestic use - 17 } Trade purposes - 11 } 28 gallons per day.
Estimated or measured dry weather flow of sewage	26,754,375 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes. Breweries, dye and bleach works, galvanising works, grease refineries, tanneries, manufactories of tar products, rubber goods works, tripe-dressing works, mineral water manufactories. 4 to 5 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm overflows are provided at certain points, which are supposed to come into action at a dilution of five to one; in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc., F.I.C. (Supt.) W. Clifford, A.R.C.Sc.I. Edward Ardern, B.Sc. (Vict.) H. D. Bell, } A. C. Oddie, } Junior Assistants. E. Hadfield, }
Name and qualification of chemist who has made the analyses.	Under the direction of G. J. Fowler (Supt.)

(1) (a) What is the capacity in gallons of the closed septic tank or tanks? — 19,620 gallons.

(b) If there was more than one tank, state whether they were worked in series or in parallel.

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion. — Once, at end of 20 months' working. About 65 tons. After 20 months' working the flow of sewage through the tank was stopped and the contents pumped out. After removing the water a stratum of about 3¾ feet was left. This was pumped out, as far as possible, by means of a chain pump. The residue which could not be reached by the pump was left in, averaging in depth about 3¼ in.; allowing for this residue, the total sludge in the tank was estimated at about 65 tons. The sludge removed contained 88·7 per cent. moisture. During the period of work the total flow of sewage through the tank was estimated at 14,400,000 gallons. Allowing 26·0 grains per gallon, suspended matter in the sewage, 240 tons of sludge, containing 90 per cent. moisture, would normally be produced. From the above results it might be calculated that not more than 30 per cent. of the total sludge requires to be dealt with in the tank. It must, however, be borne in mind that a large amount of suspended matter has found its way on to the surface of the beds, causing the level of this to rise. It is questionable also whether the sewage arriving at the septic tank contained its full proportion of suspended matter.

(3) (a) What was the water-holding capacity at commencement of experiment of the beds when filled with the filtering material? — 3,560 gallons.

(b) What was the depth of these beds? — 4 feet.

(c) What was the nature and size of the filtering material? — Screened clinker. Composed as follows from the bottom upwards:—
1 foot to pass 3 in. mesh, and rejected by 1 in.
2 foot 9 in. „ ¾ in. „ „ „ „ ⅛ in.
3 inches of residue from above, which will pass ⅛ in. mesh.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

BED No. 6.

Date.	Gallons.	Remarks.
8th November 1898	3,560	Material dry.
9th „ „	3,330	8 hours draining.
28th April 1899	2,820	8 „ „
8th September „	2,480	8 „ „
13th November „	2,500	3 days rest.
14th „ „	2,340	8¼ hours draining.
1st March 1900	2,090	8 „ „
18th „ „	2,200	44 „ „
19th June „	2,000	8 „ „

Appendix C9.

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds?

(*c*) What was the nature and size of the filtering material?

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

10 Nov.—8 Dec. 1898.	Each bed filled once a day between 6 a.m. and 6 p.m. by means of automatic gear; flow stopped during the night, and from Saturday noon to Monday morning. (*a*) 2 hrs.; (*b*) 1 hr.
8 Dec. 1898—2 Jan. 1899.	Beds Nos. 4, 5, 6 held full 2 hrs. by disconnecting gear. Flow stopped as in previous period.
2 Jan.—25 Feb. 1899.	Flow continuous (Saturday noon to Monday morning excepted). About two fillings per day on each bed. Beds 1, 2, and 3 worked by automatic gear. Cycle: (*a*) 2 hrs.; (*b*) 1 hr.; (*c*) ½ hr.; (*e*) 8½ hrs. Beds 4, 5, and 6, gear disconnected. Cycle: (*a*) 2 hrs; (*b*) 2 hrs.; (*c*) ½ hr.; (*e*) 7½ hrs.
25 Feb.—17 Mar. 1899.	Tank working 14 hrs. per day. Each bed filled twice per day. Gear disconnected. Cycle: (*a*) 1 hr. 20 min.; (*b*) 2 hrs.; (*c*) ½ hr.
17 Mar.—29 April 1899.	Tank working 18 hrs. per day. Flow stopped between noon and 6 p.m. 6 a.m.—12, noon, 1 filling on each bed. Gear disconnected. Cycle: (*a*) 1 hr.; (*b*) 2 hrs.; (*c*) ½ hr.; (*e*) 8½ hrs. 6 p.m.—6 a.m., 1 filling on each bed. Worked by automatic gear. Cycle: (*a*) 2 hrs.: (*b*) 1 hr.; (*c*) ½ hr.; (*e*) 8½ hrs.
29 April—20 Nov. 1899.	Tank working 18 hrs. per day. Flow stopped 6 a.m.—12 noon. 12 noon—6 p.m., 1 filling on each bed. Gear disconnected. Cycle: (*a*) 1 hr.; (*b*) 2 hrs.; (*c*) ½ hr.; (*e*) 8½ hrs. 6 p.m.—6 a.m., as in previous period.
20 Nov. 1899—17 Jan. 1900.	Tank working 20 hours per day. Flow stopped 1 a.m.—12 noon, and 12 noon—4 p.m., 1 filling on each bed. Gear disconnected 4 p.m.—6 p.m. Cycle: (*a*) 40 min.; (*b*) 2 hrs; (*c*) ½ hr. 6 p.m.—10 a.m., 9 fillings (2 fillings on three beds, 1 on the other three). Automatic gear. Cycle: (*a*) 1 hr. 45 min.; (*b*) 1 hr; (*c*) ½ hr.
17 Jan.—26 Dec. 1900.	Flow continuous (Saturday noon to Monday morning excepted). Each bed averages 2 fillings per day, for six days a week. Worked by automatic gear. Cycle: (*a*) 1 hr. 45 min.; (*b*) 1 hr.; (*c*) ½ hr.; (*e*) 8½ hrs.

(10) State by what method the tank liquor was distributed on the beds.

Beds, worked largely by the automatic gear of Messrs. Commerons, Commin and Martin, consist of tipping buckets, syphons, and connected wells. Tanks effluent distributed on the beds by means of channels made from half-pipes laid flush on the filtering medium.

(11) What was the average quantity of sewage in gallons dealt with daily?

23,000 gallons.

(12) Was the quantity of sewage dealt with increased in time of storm?

Rarely.

If so, state to what extent, and how the results were affected by such increase.

On one occasion extra fillings were put on, and the effluent continued good.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Daily except Sundays. Samples shaken before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

The following numbers are the average of daily analyses of the filtrate during different periods corresponding to the different methods of working.

Parts per 100,000.

Date.	Four Hours Oxygen Absorption.	Incubator Test, 3 mins. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken,

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Very little, except in the first flush, which contained much suspended matter and was often putrefactive.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of the daily analyses of the crude sewage for the quarter ending December 26, 1900:—

4 hours oxygen absorption - - -	11·46
3 minutes oxygen absorption - - -	5·47
Ammoniacal nitrogen - - - -	2·01
Albuminoid nitrogen - - - -	0·61
Chlorine - - - - - - -	16·6

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.

Begun November 10th, 1898—still proceeding. Three weeks at time of emptying sludge, other occasional days—about one month in all.

(17) Give particulars of any observations which have been made of the temperature of the contact beds at different depths.

(18) Was any nuisance caused by the experimental works?

Very slight smell near the aerator channel.

(19) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Yes.

(20) Give particulars of any other observations of importance which were recorded.

Effect of Trade Refuse.—On December 2nd, 1899, an accidental discharge of ammonia recovery liquor into the sewer raised the oxygen absorption figure of septic tank effluent to upwards of 24 grains per gallon; this was reduced by the filters to 2·56, and no subsequent ill effects were noted.

First Flush and Drainage.—While the first flush from the bed was turbid and often putrefactive, the effect was not considered serious, as it did not last more than a few minutes; the drainings from the bed after emptying attain a high degree of purity, and when these are mixed with an equal volume of the first flush, the mixture is in general non-putrefactive.

Appendix 9C.

Effect of Filtrate on the Ship Canal Water.—A number of experiments have shewn that the filtrate from this installation contains enough residual oxygen dissolved and combined as nitrate to purify its own bulk of Ship Canal water.

Effect of Aerator.—No appreciable chemical difference could be detected in the tank effluent before and after it had passed the aerator. It is quite possible, however, that the liberation of the dissolved gases thus produced may excite a beneficial effect.

Gas produced in Septic Tank.—The gas obtained from the closed septic tank was found to be similar in composition to that evolved from the open septic tank, consisting chiefly of marsh gas with a small percentage of hydrogen and carbon dioxide.

Automatic Gear.—When all the working parts are in good condition the apparatus is capable of working smoothly and well. The corrosive action of the partially-purified septic tank effluent tends however to loosen any screws or nuts exposed to it and the pipes also are liable to become coated with deposit. Frequent attention is necessary from these causes. It was noticed that when a bed is tight on the surface, the water will not penetrate fast enough to enable the flow to be diverted from the bed before considerable ponding has taken place on the surface.

Maintenance of Beds.—The surfaces of the beds have been periodically raked and occasionally forked up to a depth of about 6 in. In process of time the surface has risen above the level of the distributing channels to an extent of some 6 in., the material having the general character of garden soil, which finally tends to impede the filling of the beds. If, however, this upper layer be removed, the clinker below is fairly loose. In one or two cases the upper layer has been removed, and on again putting the bed into use, it takes the freely, and in process of time the layer is reformed.

(21) What inferences have been drawn from the experiment?

Trade Refuse.—Save in exceptional circumstances, trade refuse as ordinarily met with is not seriously prejudicial to the working of this process, while the blending which takes place in the septic tank tends to obviate the effect of sudden rushes of manufacturing waste. The effect of iron pickle in the case of Manchester sewage is to cause more rapid silting-up of the septic tank and to increase the deposit on the beds, but it is not otherwise of serious effect.

Automatic Gear.—One difficulty of apparatus depending for its working on the rate of flow of sewage is that the cycle must vary with the flow, and is shortest when this is at its height; an increased flow, however, in dry weather coincides with the strongest sewage, and therefore some method of ponding up would have to be resorted to in this case. In the experiments described, the flow was kept pretty constant throughout the day. An inherent difficulty with automatic gear depending on the sewage flow is that the cycle of one bed is dependent on the condition as to capacity, character of surface, &c., of another bed, which will vary according to circumstances, length of working, weather, &c.

Maintenance of Beds.—It appears to be necessary that the surface of the beds should be raked about once a month. After about two years the surface of the beds should be removed and piled, in order to completely weather. In the meantime old weathered material may be spread on the surface. At rarer intervals, say five years, the clinkers below the surface may require to be washed to the depth of about one foot.

Number of Fillings.—The beds may safely take two fillings of septic tank effluent per day, after deducting all periods of rest.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

GILBERT J. FOWLER,
Signature of officer under whose direction the experiment was conducted.

Appendix 9C.

Form A.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CLOSED SEPTIC TANK AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority - - - - - - - -	Slaithwaite Urban District Council.
Population of district - - - - - -	4570.
Water supply per head of the population - - -	gallons per day.
Estimated or measured dry weather flow of sewage -	100,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Surface water is excluded.
Officer under whom the experiment has been conducted -	Chairman of the Sanitary Committee, who is a manufacturing chemist.

Name and qualification of chemist who has made the analyses.	
(1) (*a*) What is the capacity in gallons of the closed septic tank or tanks?	100,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	In parallel.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	No.
If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Single contact fine beds only used.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	About 12,000 gallons.
(*b*) What was the depth of these beds? - - -	5 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Furnace clinkers rejected by a ¼-inch screen.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	No change after working nearly two years.
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	2 hours filling; 1 hour in contact. Average 3 fillings in 2 days.

Appendix 9C.

(10) State by what method the tank liquor was distributed on the beds.	Distributing troughs laid on the surface of the beds.
(11) What was the average quantity of sewage in gallons dealt with daily?	130,000 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	About 3 fold. No appreciable difference in effluent.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	
(14) Give (*a*) the average of the analyses of the final effluent from the beds;	
(*b*) the best analysis of the final effluent and date when sample was taken; and	
(*c*) the worst analysis of the final effluent and date when sample was taken;	Certified "very satisfactory" by the Inspector to the West Riding Rivers Board.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(15) Give a typical analysis of the crude sewage to which the experiment relates.	
(16) Between what dates was the experiment conducted?	
If there were any periods of rest, state their duration?	None.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	None.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - - -	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Certainly.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	The process is eminently satisfactory for domestic sewage.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	About 5*s*. per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	About 3*d*. per head per annum.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

JAS. WOODHEAD,
Chairman of the Sanitary Committee.
Signature of Officer under whose direction the experiment was conducted.

Form A.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CLOSED SEPTIC TANK AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority - - - - - - - -	Corporation of York.
Population of district - - - - - - -	About 75,000.
Water supply per head of the population - - -	33 gallons per day.
Estimated or measured dry weather flow of sewage -	45 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse:	Trade refuse is so small as to be negligible.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Storm water above the capacity of the sewers, yes. Soil or surface, no.
Officer under whom the experiment has been conducted -	City Engineer.
Name and qualification of chemist who has made the analyses.	(*a*) Thomas Fairley, F.I.C., F.R.S. Edin., F.C.S. London, etc., etc. (*b*) Edmund Moody Smith, M.D., C.M. Edin., D.P.H. Cam., Medical Officer of Health, York.

(1) (*a*) What is the capacity in gallons of the closed septic tank or tanks?	40,000.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	Only one.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Yes, not more than 4 in. of sludge has been observed.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	The sludge has not been removed.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Not ascertained. There were 4 beds filled as described in (3) (*c*).
(*b*) What was the depth of these beds? - - -	3 feet.
(*c*) What were the nature and size of the filtering material?	Cinder, Coke, and Clinker.

—	No. 1.	No. 2.	No. 3.	No. 4.
	Ft. In.	Ft. In.	Ft. In.	Ft. In.
Rejected by $1\frac{1}{4}$ in. screen	– 3	—	—	– 3
$\frac{7}{8}$ in. to $1\frac{1}{4}$ in. -	1 3	—	—	—
$\frac{3}{8}$ in. to $\frac{3}{4}$ in. -	1 6	1 6	1 6	2 9
Rejected by $\frac{3}{4}$ in. screen	—	1 6	1 6	—
Total -	3 –	3 –	3 –	3 –

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Not ascertained.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	Not ascertained.
(6) (*a*) What was the water-holding capacity at the commencement of experiment of the fine beds when filled with the filtering material?	There were no fine beds as distinguished from those described in (3) (*c*).
(*b*) What was the depth of these beds? - - -	
(*c*) What were the nature and size of the filtering material?	
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	

Appendix 9C.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.* number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

As a rule:—
Three fillings per day of 24 hours, (*a*) 2 hours, (*b*) 2 hours, (*c*) $1\frac{1}{2}$ hours, (*e*) $2\frac{1}{2}$ hours. This was varied on occasions, but no better or worse results were obtained.

(10) State by what method the tank liquor was distributed on the beds.

By means of three semi-circular troughs.

(11) What was the average quantity of sewage in gallons dealt with daily?

About 40,000 gallons.

(12) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

1st August 1899; 19th October 1899; 22nd November 1899; 6th, 14th, 21st and 29th September 1900.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

Total solids	72·01
Mineral matter	63·88
Volatile and organic matter	8·126
Free ammonia	3·41
Albuminoid ammonia	0·269
Nitrogen as calcium nitrate	under 0·01
Nitrogen as nitrites	nil
Oxygen required to oxidise organic matter in 4 hours	1·151
Reaction	Alkaline
Chlorine	12·03
Sediment	0·24
Containing organic matter	trace
Analyst	Mr. Fairley

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

—	Best.	Worst.
	19 Oct. 1899	1 Aug. 1899
Total solids	67·51	76·7
Mineral matter	63·2	64·2
Volatile and organic matter	4·31	12·5
Free ammonia	2·23	1·657
Albuminoid ammonia	0·157	0·257
Nitrogen as calcium nitrate	Nil	Under 0·01
Nitrogen as nitrites	Nil	Nil
Oxygen required to oxidise organic matter in 4 hours	0·67	1·57
Reaction	Alkaline	Alkaline
Chlorine	10·21	14·54
Sediment	1·68	Nil
Containing organic matter	Nil	Nil
Analyst	Mr. Fairley	Mr. Fairley

"Best" and "Worst" are so judged by "Oxygen (4 hours)."

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.

Not ascertained.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Trace only, on one occasion there was 1·68. Not putrescible.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Total solids	84·27
Mineral matter	69·47
Volatile and organic matter	14·8
Free ammonia	5·21
Albuminoid ammonia	0·386
Nitrogen as calcium nitrate	Nil
Nitrogen as nitrites	Nil
Oxygen required to oxidise organic matter in 4 hours	4·157
Reaction	Alkaline
Smell (when cold)	very offensive
Chlorine	10·64
Sediment	21·83
Containing organic matter	17·7
Analyst	Mr. Fairley

Appendix 9C.

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	22nd April, 1899, to 28th October, 1900. Each filter was allowed a week's rest alternately.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	No observations.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	Yes, but with reconstructed beds, the sides being now of brickwork.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	No observations in connection with this experiment. I should like, however, to place on record an experiment made with two plots of land, each one-eighth of an acre, spade trenched over 2 ft. in depth and under-drained. The land experimented upon is characteristic of the whole district. 14th June, 1899, commenced at 8 a.m. to run septic tank filtrate on to each plot alternately until August 16th, when it was stopped; each bed was worked alternately for 12 hours and then rested for 12 hours. The reason for stopping this experiment was that the land was not taking the effluent; it was passing out some other way. An analysis made on August 1st by Mr. Fairley showed septic filtrate ·18 albuminoid ammonia and 1·1 oxygen absorbed in 4 hours in grains per gallon, while the filtrate from land showed ·15 albuminoid ammonia and ·79 oxygen. The second contact bed effluent at the same time showed ·14 albuminoid ammonia and ·67 oxygen. On the 4th November Colonel Slacke, Local Government Board Inspector, made an inspection of the works. The day before his visit septic tank effluent or filtrate had again been turned on to the land. It should be stated that the effluent was still standing on the land 15 days after the last flooding on the 16th August. As showing the unsuitability of the land for filtration of sewage, a hole about 1 ft. 6 in. long by 9 in. wide and 12 in. deep was made in one of the shallow furrows in Plot 2, the septic filtrate running along the furrow immediately filled the hole. A second hole of similar size was made on the ridge immediately adjoining at a distance of 9 in. from the first hole; this was perfectly dry, the intervening space was gradually sliced away until only 1½ in. of soil separated the two holes. There was still no moisture in the second hole. A pencil was then forced into the slight barrier for ¾ in.—still no moisture—and it was only when the pencil was passed through to the first hole that a slight trickle came through into No. 2. By this time the side of No. 2 nearest to No. 1 showed signs of sweating.
(21) What inferences have been drawn from the experiment?	That the system is superior to chemical precipitation, but not equal to either (1) Double contact beds; (2) open septic and contact beds; or (3) open septic and continuous filtration. We have been disappointed with the results of the closed septic tank and beds.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	It is practicable but not desirable, as other experiments have given better results.
(a) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	No estimate has been prepared.
(b) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Ditto. ditto.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen - - - - - Albuminoid nitrogen - - - - - Nitrous nitrogen - - - - - Nitric nitrogen - - - - - - Total organic nitrogen - - - -	This cannot now be done; the analyses are given as received. A standard form for sewage analyses is very much needed.

A. Creer.
Signature of officer under whose direction the experiment was conducted.

Appendix 9C.

Form A.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CLOSED SEPTIC TANK AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority - - - - - - -	Sefton Rural District Council.
Population of district - - - - - - -	(Portion Kirkby Park) 80.
Water supply per head of the population - - -	27 gallons per day.
Estimated or measured dry weather flow of sewage -	1600 gallons per day.
Is any trade refuse taken into the sewers? - - -	Domestic, no trade refuse.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially excluded.
Officer under whom the experiment has been conducted -	Building Surveyor and Sanitary Inspector.
Name and qualification of chemist who has made the analyses.	

(1) (*a*) What is the capacity in gallons of the closed septic tank or tanks?	4,000.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel	Only one tank.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Yes.—Once.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	Contained about 90 cubic ft. Matter in suspension being noticed in the effluent, which was clogging the beds, the tank was opened November 23, after being in operation 8 months. A black dense scum 7 inches thick was found on top, containing half rotten paper, corks, matches, and fibrous material. Upon opening the valve (fixed 14 inches above the floor of tank for emptying) the contents subsided to its level. On further examination found:—Scum 7 inches thick, water 3 inches, deposit 4 inches, suspended matter in effluent due to obstruction in storm-overflow, allowing storm water to pass into tank.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	250 gallons.
(*b*) What was the depth of these beds? - - -	1 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	$\frac{3}{4}$ in. and $\frac{1}{2}$ in.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No reliable measurements, but estimate the beds have little more than half the water-holding capacity as at first.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and if so, what was the duration of the resting?	
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	1 ft. 6 in.
What were the nature and size of the filtering material?	$\frac{1}{2}$ in. to $\frac{3}{8}$ in.
Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	Same as coarse bed.
(*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting and, if so, what was the duration of the resting?	

Appendix 9C.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	*a*. 5 or 6 times. *b*. Varying from ½ to 1 hour according to flow. *c*. 10 minutes. *e*. Varying from ½ to 1 hour.
(10) State by what method the tank liquor was distributed on the beds.	Direct by automatic syphons (no troughs).
(11) What was the average quantity of sewage in gallons dealt with daily?	1,600 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Yes. Improved by dilution, not good afterwards.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	
(14) Give (*a*) the average of the analyses of the final effluent from the beds.	
(*b*) the best analysis of the final effluent and date when sample was taken, and	
(*c*) the worst analysis of the final effluent and date when sample was taken.	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	None discernible to the eye.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Good at first, but bad as filters began to sludge up after 6 months, constant work.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	None taken.
(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	None.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	None taken, but on two occasions ice ¼ in. thick formed over the portion containing syphon in the coarse bed. No ice on fine bed.
(18) Was any nuisance caused by the experimental works?	None.
(19) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	Under alteration for the purpose of experiment for the precipitation of matter in solution.
(20) Give particulars of any other observations of importance which were recorded.	Any offensiveness noticed at the time of the discharge of filtrate had completely disappeared by the time it reached Waddagor Lane, 370 yards distant. It had evidently become oxidized and clarified during its passage down an open ditch for this distance.
(21) What inferences have been drawn from the experiment?	The filter area is insufficient in this case. Filters should receive a fixed quantity at a time from a measuring tank. Filters should be of sufficient capacity to work only once a day. Storm water, except in very small quantities, should be excluded. Double contact is necessary.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	£2 11*s*. 0*d*.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	Nil.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

F. Pool.

Signature of officer under whose direction the experiment was conducted.

Appendix 9C. Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN CHANNEL AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority	Carlisle.
Population of district	42,000, estimated.
Water supply per head of the population	29·45 gallons per day.
Estimated or measured dry weather flow of sewage	1,317,000 gallons per day. In addition to the above a quantity of clean subsoil water finds its way into the sewers.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes. Liquid waste from dyeing processes, wool scouring, engine and condensing water. Waste water from felt washing at hat works. About 38 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	Henry C. Marks, City Engineer.
Name and qualification of chemist who has made the analyses.	Dibdin and Thudichum, London.

(1) (*a*) What is the capacity in gallons of the open channel or tanks?	22,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	Only one channel.
(2) Were any observations made as to the filling up of the channel by deposit of sludge?	Yes.
If the sludge was removed from the channel, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	Sludge accumulated until septic action was established, and it then disappeared, becoming soluble. No deposit has taken place since.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	50,600 gallons average.
(*b*) What was the depth of these beds?	Averaging 3 ft. 10 in.
(*c*) What were the nature and size of the filtering material?	Red sandstone broken into large pieces varying from 1 in. to 5 in. in diameter.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	In work.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	Present capacity 46,600 gallons. Beds still working. Each bed rests about 24 hours per week.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No fine beds.
(*b*) What was the depth of these beds?	No fine beds.
(*c*) What were the nature and size of the filtering material?	No fine beds.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	No fine beds.
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Almost three. Filling - 1¾ hours Standing full - 2 „ Emptying - 3¼ „ Resting - 2 „ 9
(10) State by what method the tank liquor was distributed on the beds.	Open wooden troughs.

11) What was the average quantity of sewage in gallons ealt with daily?	June to August - - - - - 200,000 gallons. August to November - - - 450,000 „ Since November - - - - - 466,000 „ 3)1,116,000 372,000
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No, we pump our sewage from the outfall sewer as we require it.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	July 10th, August 16th, October 23rd, November 27th, 1900. January 9th, 1901. Settled.
(14) Give (*a*) the average of the analyses of the final effluent from the beds. (*b*) the best analysis of the final effluent and date when sample was taken, and (*c*) the worst analysis of the final effluent and date when sample was taken.	Fine beds not constructed.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	18·4 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the coarse bed effluent. Were these putrescible?	4·8 parts per 100,000. No fine beds yet.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	Chlorine - - - - 6·3 parts per 100,000. Ammoniacal nitrogen - - 2·000 „ Albuminoid nitrogen - - 0·324 „ Oxygen absorbed in 4 hours - 3·71 „ Suspended matters - - 24·0 „
16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration	June to present date. 24 hours each week, and for short periods due to temporary engine breaking down.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	Not taken.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes. Yes.
(20) Give particulars of any other observations of importance which were recorded.	The work has been interrupted in consequence of the pumping arrangements being incomplete, with the result that after each resumption of work the effluents were not up to the quality of those obtained when the beds had been working systematically.
(21) What inferences have been drawn from the experiment?	That the sewage can be purified by these very coarse beds to the following extent:— *Sewage between 6 a.m. and 1 p.m. November 27th, 1900.* Suspended matters reduced by 81·0 per cent. Dissolved impurities albuminoid nitrogen by 30·9 per cent. Dissolved impurities oxygen absorbed by 26·9 per cent. These effluents maintained their aeration fairly well. The beds had been working steadily for about two months. *Sewage between 2.45 p.m. and 9 p.m. January 8th, 1901.* Suspended matters reduced by 76·8 per cent. Dissolved impurities albuminoid nitrogen by 31·7 per cent. Dissolved impurities oxygen absorbed by 23·1 per cent. The effluents did not maintain their aeration for 24 hours. The working of the beds had been interrupted by the pumping arrangements.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state (*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers. (*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Yes.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Henry C. Marks,
City Engineer.
Signature of officer under whose direction the experiment was conducted.

Appendix 9C.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority - - - - - - -	Haslingden, Rawtenstall, and Bacup Outfall Sewerage Board.
Population of district - - - - - - -	73,000.
Water supply per head of the population - - -	25 gallons per day.
Estimated or measured dry weather flow of sewage -	Two million gallons per day.
Is any trade refuse taken into the sewers? - - - - If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No. The sewers are only constructed for domestic sewage requirements. Some dye works or print works refuse has by accident got in. The source is not yet traced
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially. The surface water is, where practicable, turned into the river.
Officer under whom the experiment has been conducted.	The replies refer to the whole works.
Name and qualification of chemist who has made the analyses.	The analyses of the Mersey and Irwell Joint Rivers Committee have been taken.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	About 2,000,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	Four tanks, each 180 feet, long by 60 feet average depth 7½ feet. All at work together.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Yes. There is only a small deposit. On 5th February, 1900, it was reported that the deposit of sludge in 9 weeks was less than deposit under chemical precipitation for 4 weeks.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	None has been removed since, and the deposit of sludge has not increased to any extent.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	The artificial filter beds are 16 in number, each 45 feet long by 30 feet wide and 5 feet deep. Total area 2,400 superficial yards.
(*b*) What was the depth of these beds? - - -	5 feet, filtering media 3 feet deep.
(*c*) What were the nature and size of the filtering material?	Filters constructed as follows:—4 inch drain tiles on the floor surrounded with burnt ballast, 8 inches of coarse coke, 4 inches of burnt ballast with aerating pipes laid in same, 14 inches of coarse and fine coke mixed, the whole covered with 6 inches of fine clinker cinders.

Note.—In actual working it was found that a thin scum formed over the top layer of finer material, causing a clogging in the working unless constantly cleaned. It has now been found that coarse clinkers and coke of the size of a walnut or a little larger is much more effectual than the fine clinker cinders, which are being gradually replaced.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	None made.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	This is not an experiment but work in actual use, and they are still in use.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Have none. The coarse filter filtrate is passed on to land for final treatment.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	

Appendix 9C.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	The contact beds are worked as follows: They are filled twice during the day (12 hours). The filling takes about three hours, they stand full one hour; they are then run off in about two hours, and rest during the night for 12 hours.
(10) State by what method the tank liquor was distributed on the beds.	By carriers and penstocks and valves with side distributing troughs.
(11) What was the average quantity of sewage in gallons dealt with daily?	The works filter and land deal with 2,000,000 gallons daily.
(12) Was the quantity of sewage dealt with increased in time of storm?	The storm increase was dealt with by storm overflows working when sewage diluted eight times.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to settle before being analysed.	None were made except those of the Inspectors of the Mersey and Irwell Joint Rivers Committee.
(14) Give (*a*) the average of the analyses of the final effluent from the beds. *Note.*—The analyses are of the filtrate after land treatment as well as beds.	Oxygen absorbed four hours test, grains per gallon, ·94.
(*b*) the best analysis of the final effluent and date when sample was taken, and	November 13, 1900. 3 p.m. Fine weather, heavy rain previous day. Oxygen absorbed four hours test, grains per gallon, 0·28.
(*c*) the worst analysis of the final effluent and date when sample was taken.	July 13, 1900. 1.15 p.m. Fine weather. Oxygen absorbed as before, 1·38.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	None made.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	None made.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	see table below

	Grains per gallon.
Chloride combined	4·26
Ureal ammonia	0·868
Albuminoid ammonia	0·476
Oxygen absorbed from permanganate of potash at 80° F. in four hours	2·80
Total solids	48·00
Mineral	32·00
Volatile	16·00

Hardness, 35 degrees.

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	The observations furnished are on the working of the whole works.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	The works are still being carried on in the same way. The saving between this and the old chemical precipitation system being over 1,000*l.* a year.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes. Certainly.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state.	As before stated the disposal of the whole sewage is effected by this means.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	It is impossible to say. So much depends on the adaptability of the soil (*i.e.*, clay land may not require concrete works, &c.), and the nature of the construction.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	4*s.* 6*d.*

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

RICHD. WM. BUGLER.
Clerk to the Board.

Appendix 9C.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority - - - - - - -	Hendon Urban District Council.
Population of district - - - - - -	22,500. About 18,000 to 19,000 drained to outfall works at present.
Water supply per head of the population - -	About 35 gallons per day.
Measured dry weather flow of sewage - - - -	700,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Laundry work may be regarded as the staple industry of the place. This is also a residential suburb of London.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	In nearly all the roads there is a separate surface water drain as well as a sewer, and such surface water drain takes the water from the front roofs of most of the houses as well as all the surface water from the roads themselves.
Officer under whom the experiment has been conducted	Engineer and Surveyor.
Name and qualification of chemist who has made the analyses.	Mr. Frank W. Andrew, M.R.C.S., L.R.C.P., Medical Officer of Health for Hendon. Dr. Houston (crude sewage and resulting effluent from Col. Ducat's Filters). Dr. Bevan, County Analyst.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	Only one tank out of the six chemical precipitation tanks referred to in Form "C." has been used as an open septic tank. (5th November, 1900.)
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	About one foot of sludge appears to have collected on the bottom of the tank in two and a-half months.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion	No sludge has been removed up to the present.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	We have only one set of contact beds at present, consisting of three bacteria beds, each of 800 yards superficial area and five feet deep. Bed No. 1 was constructed in September 1898, bed No. 2 September 1899, bed No. 3 December 1900; cost of each bed which is surrounded with concrete walls and floor averages 1,000 *l.* each; 3,000 *l.* the three beds.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	$\frac{3}{4}$ in. clinker pan breeze rejected by a $\frac{1}{8}$ in. sieve which removed the fine stuff.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Each of the beds holds about 120,000 gallons of sewage. Effluent at one filling and no reduction in capacity has been noticed at present.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	See No. 4.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No "fine" beds at present.
(*b*) What was the depth of these beds?	
(*c*) What was the nature and size of the filtering material?	

Appendix 9C.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

No fine beds at present.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

Each bed filled and emptied once a day only, resting all night and Sundays.

(10) State by what method the tank liquor was distributed on the beds.

After passing through an area of two acres of land, laid out on the intermittent downward filtration principle, the effluent from such intermittent downward filtration area is discharged on to the coarse bacteria beds by concrete carriers and galvanized iron sluices in the carriers.

(11) What was the average quantity of sewage in gallons dealt with daily?

(12) Was the quantity of sewage dealt with increased in time of storm?

Yes.

If so, state to what extent, and how the results were affected by such increase.

With 1 in. rain in 24 hours if during rainy time, the dry weather flow is increased four times, *i.e.*, to 2,000,000 gallons. A better effluent obtained with small quantity of rain, compared with effluent during a dry summer.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Samples allowed to settle, made from time to time, not at stated or regular intervals.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

Free ammonia 1·4 parts per 100,000.
Alb. „ ·14 „ „ „
The amount of albuminoid ammonia in the crude sewage has been found by Dr. Houston as high as 7·6 per 100,000, and by Dr. Bevan 8·4 parts per 100,000. The albuminoid ammonia is never less than 3 parts per 100,000 on an ordinary day and in dry weather is much more frequently run up to 8 parts per 100,000 and over.

(*b*) the best analysis of the final effluent and date when sample was taken; and

Alb. NH_3 ·13 per 100,000 on 13th February 1899.

(*c*) the worst analysis of the final effluent and date when sample was taken;

Alb. NH_3 ·17 per 100,000 on 18th May 1900.

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

Cannot give this.
Dr. Barwise found in the crude sewage 315 parts of solid matter per 100,000, 198·5 parts of which were in suspension.
20th November 1897:
Free ammonia 6·16 parts per 100,000.
Organic ammonia 3·8 parts per 100,000.
Professor Corfield found on 10th May 1898:
Total solids 265·3 parts per 100,000.
Fixed 115·1 parts per 100,000.
Volatile 150·2 „ „ „

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Dr. Bevan:

Total solids dried at 212° F.	13·4
Solids in suspension	none
Solids in solution	130·4
Mineral matter in solution	1·43
Alb. Ammonia	·143
Oxygen consumed in 32 hours	·51
Chlorine	14·3

Dr. Bevan states that the percentage of purification effected is 93 per cent. on the albuminoid ammonia and 82 per cent. on the oxygen.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

See 14 (d) ante.

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.

September 1898 and still going on.
Sundays. Bacteria beds, always resting.
Week days. Each bed filled once a day.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.

It has been noted that during the time sewage effluent was in contact with the filtering media in bacteria beds, temperature increased on an average 1 degree F. only (thermometer placed two feet below surface of bed)

Appendix 9C.

(18) Was any nuisance caused by the experimental works?	There is none. (Far less than on the land.)
(19) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	With pleasure any time.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	That it has been demonstrated beyond a doubt that open septic or detritus tanks with a capacity of not less than one day's dry weather flow with subsequent filtration through land laid out on the intermittent downward filtration principle and afterwards contact with bacteria will produce an effluent which is not injurious to fish life as the volume of the effluent is about 10 times the volume of the flow in the River Brent, into which it discharges, as for many weeks in the year the volume of water flowing in the River Brent is under 22,000 gallons, gauged by S.S. Grimley. It will be noted that the sewage is particularly foul, being little more than a solution of soap on three days a week, in addition to the dense domestic sewage on all days. A better effluent can be obtained from artificial bacteria beds than from the clay land forming the site of the outfall works.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Quite practicable.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	10*s*. per head first cost of bacteria beds in addition to the present open septic or detritus tanks.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	2*l*. 10*s*. to 3*l*. per million gallons of dry weather flow. If all the water were taken into account, the mean would be 25*s*. to 30*s*. per million gallons treated, but it is far better to take the cost on the dry weather flow. Let this be understood to be uniform throughout the replies, *i.e.*, cost to be given on the dry weather flow, which is the only reliable data.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

S. Slater Grimley,
Assoc. Member Inst. C.E.

Signature of Officer under whose direction the experiment was conducted.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS (SINGLE CONTACT).

Appendix 9C.

Name of authority - - - - - - - -	County Borough of West Bromwich.
Population of district - - - - - - - -	(1891). 59,489.
Water supply per head of the population - - -	20 gallons per day.
Estimated or measured dry weather flow of sewage -	About 400,000 gallons per day, high level sewage.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	None.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Wholly excluded.
Officer under whom the experiment has been conducted.	Borough engineer and surveyor.
Name and qualification of chemist who has made the analyses.	H. Silvester, F.I.C., F.C.S., borough analyst.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	50,000 (25,000 each).
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	Two tanks, worked both in parallel and in series.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	Yes; one of the tanks was used only from October 3rd, 1899, to September 12th, 1900, it was then run out and about 100 cubic yards of sludge was found in it.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	About 16,666 gallons, taking it at one-third of the capacity of bed.
(*b*) What was the depth of these beds?	3 feet.
(*c*) What were the nature and size of the filtering material?	Screened engine ashes ½-inch to 2-inch mesh.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	After the bed had worked twelve months, and had treated during that time 816 fillings, a meter was fixed at the outlet and readings taken.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	9,950 gallons, average of twelve readings.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material? (*b*) What was the depth of these beds? (*c*) What were the nature and size of the filtering material?	After the sewage had been treated in the coarse-grained beds it was passed on to the land which had been underdrained and took the place of fine-grained beds.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment? (*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Three fillings every 24 hours, Sundays excepted, (*a*) 1½ hours, (*b*) 2 hours, (*c*) emptying, 1½ hours, resting 3 hours every 8 hours.
(10) State by what method the tank liquor was distributed on the beds.	By iron troughs.
(11) What was the average quantity of sewage in gallons dealt with daily?	Estimated at 45,000 gallons at commencement.
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No. 1.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Samples analysed at various dates between November, 1899, and September, 1900, 18 in all.
(14) Give (*a*) the average of the analyses of the final effluent from the beds	*See* following tables.

ANALYSES of SAMPLES of SEWAGE and EFFLUENTS after Bacteria Treatment from Friar Park Sewage Farm, West Bromwich, by H. Silvester, F.I.C., F.C.S., Borough Analyst.

(Quantities stated in parts per 100,000.)

HIGH LEVEL.

Date.	Sample No.	No. of filling.	CRUDE SEWAGE.

* Samples 1, 2, and 6 were taken after sewage had passed through detritus tanks, hence matter in suspension is low. Samples 6 and 11 dilute sewages, owing to heavy rainfall.

(*b*) the best analysis of the final effluent and date when sample was taken ; and	
(*c*) the worst analysis of the final effluent and date when sample was taken ;	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed ;	60·97 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible ?	·66 parts per 100,000.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	*See* foregoing tables.
(16) Between what dates was the experiment conducted ? If there were any periods of rest, state their duration.	Commenced 12th September, 1899, and extended to 1st November, 1900. Beds rested from 5th December to 12th December, 1899, and Sundays.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	

HIGH LEVEL (Cross-grained Bed).

(18) Was any nuisance caused by the experimental works ?	None whatever.
(19) Is the experiment still proceeding ?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so ?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	*See* report enclosed.
(21) What inferences have been drawn from the experiment ?	*See* report enclosed.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	The scheme proposed by me, and lately adopted for the treatment of the whole of the sewage of the borough includes detritus or open septic tanks.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	About 5*s*.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	*See* answer to same question on Form L.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammonical nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Albert D. Greatorex, Assoc. M. Inst. C.E.,
Borough Engineer and Surveyor.
Signature of Officer under whose direction
the experiment was conducted.

Appendix 9C. Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority - - - - - - - -	Batley Corporation.
Population of district - - - - - - - -	30,000.
Water supply per head of the population - - -	For domestic purposes 12 gallons per day; for trade purposes 26 gallons per day.
Measured dry weather flow of sewage - - - -	500,020 gallons per day.
Is any trade refuse taken into the sewers? - - -	Yes, from wool washers, blanket makers, woollen manufacturers, dye works, carbonizers.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	About half the dry weather flow. *Note.*—There are very few water closets in this borough.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted	Oscar J. Kirby.
Name and qualification of chemist who has made the analyses.	None made yet.
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	240,000.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	Not worked in series.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Yes.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	At the end of the first week 50,000 gallons of creamy sludge were let off from the bottoms of the tanks. This quantity was gradually reduced week by week for 15 weeks, since which (12 months, viz.:—January 13th, 1900) there has not been any sludge let off.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	*Note.*—Two beds, 20 feet by 20 feet, and 3 feet 6 inches deep were put into use. Two months ago (November 9th), the high level bed has decreased in holding capacity from 38 per cent. to 27 per cent. And the low level bed from 38 per cent. to 33 per cent.
(*b*) What was the depth of these beds?	*See* above.
(*c*) What were the nature and size of the filtering material?	Furnace clinker broken to pass a 1½-inch screen, and rejected by ⅛-inch screen.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	The measurements were taken after resting in the ordinary way.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and if so, what was the duration of the resting?	
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	The material is the same size in both beds.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	3 fillings a day. *a.* 2 hours filling. *b.* 2 hours standing full. *c.* 2 hours emptying. *d.* 2 hours resting.
(10) State by what method the tank liquor was distributed on the beds.	By distributing channels.

(11) What was the average quantity of sewage in gallons dealt with daily?	8,000 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to settle before being analysed.	
(14) Give (*a*) the average of the analyses of the final effluent from the beds;	*Note.*—Dr. M. Wilson, Chief Inspector of the West Riding Rivers Board, is by his staff about to make some analyses at these works, copies of which shall be sent on to the Commission.
(*b*) the best analysis of the final effluent and date when sample was taken; and	
(*c*) the worst analysis of the final effluent and date when sample was taken;	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	No. They are not.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	
(16) Between what dates was the experiment conducted?	From November 9th to the present date.
If there were any periods of rest, state their duration.	The beds rest all day on Sundays.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	None made.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes, certainly.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	The following, viz. :—As the final effluent is only slightly cloudy (after standing 12 hours it is quite bright), and has no tendency to secondary putrefaction, it is quite possible to purify sewage containing a substantial proportion of trades wastes, by open septic tanks and double contact beds.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes.
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers	Ten shillings.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Eight pence.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

O. J. KIRBY,
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Borough of Guildford.
Population of district	17,000.
Water supply per head of the population	30 gallons per day. This quantity includes the supply of water to the railway authorities, but for which the supply per head of population would not greatly exceed 20 gallons.
Estimated or measured dry weather flow of sewage	480,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	The refuse from three breweries approximately one-third the dry weather flow.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Only partially excluded.
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses.	
(1) (a) What is the capacity in gallons of the open septic tank or tanks.	148,000.
(b) If there was more than one tank, state whether they were worked in series or in parallel.	One only in use at present.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge.	Weekly observations have been made.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	No sludge has yet been removed, and although at least 50,000,000 gallons of sewage has passed through this tank, the solids at the bottom average only 14 inches deep, whilst the scum on the top is 25 inches thick.
(3) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	25,000 gallons per bed, which multiplied by 5 (the number of beds) gives 125,000 gallons dealt with in each working.
(b) What was the depth of these beds?	Two feet nine inches.
(c) What were the nature and size of the filtering material?	Burnt ballast and clinker rejected by a ½-inch mesh screen, the material after screening to pass through a 3-inch ring.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No measurements have been taken, but very little difference in the water capacity of the coarse beds has been observed since the filters were first used, now some eight months ago.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	
(6) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(b) What was the depth of these beds?	2 ft. 6 in.
(c) What were the nature and size of the filtering material?	Burnt ballast and clinker which passed a ½-in. mesh, but was rejected by a $\frac{1}{16}$-inch mesh, dust to be carefully excluded.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (a) What was the water-holding capacity of fine beds at end of experiment?	No material difference has been noticed in respect to the fine beds consisting of burnt ballast, but the clinker beds have made up somewhat during the six months they have been in use, which in my opinion is due to the fact that the dust was not carefully excluded.
(b) Was this measurement made after resting, and, if so, what was the duration of the resting?	

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying and (*e*) resting.	Two fillings in the 24 hours as follows:— Filling - - 1 to $1\frac{1}{2}$ hours. Standing full - 2 hours. Emptying - 1 to $1\frac{1}{2}$ hours. Resting - - 2 hours.
(10) State by what method the tank liquor was distributed on the beds.	Simply allowed to run on the beds through tren[illegible] into the media.
(11) What was the average quantity of sewage in gallons dealt with daily?	250,000 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	The only analysis yet made was through the kindness of the Borough Engineer of Croydon, who was interested in the percentage of purification at once observable by the sewage passing through scum tank. I submit herewith a copy of same, in which it will be noticed an excellent effluent is obtained by intermittent filtration of the effluent from the second contact beds through an experimental tertiary bed, consisting of sand or dust excluded in the sieving of the media for the second or fine beds.

CROYDON CORPORATION, BEDDINGTON FARM,
December 10th, 1900.

THOS. WALKER, Esq., C.E., Borough Engineer.

Dear Sir,—The following are the results of analyses of samples received from the Borough Engineer of Guildford. I received them on the 6th inst., and they are marked as taken on the 4th.

SEWAGE.

Oxygen absorbed, 15 mins.	8·48 grains per gallon.
„ „ 4 hours	17·03 „ „
Chlorine	9·0 „ „
Ammonia, free	115·28 parts per million.
„ Albuminoid	35·77 „ „
Appearance	Opaque; very dark colour; large amount of suspended matter.

EFFLUENT, OPEN SEPTIC TANK.

Oxygen absorbed, 15 mins.	2·92 grains per gallon.
„ „ 4 hours	7·17 „ „
Chlorine	6·1 „ „
Ammonia, free	77·70 parts per million.
„ Albuminoid	11·72 „ „
Appearance	Opaque; offensive smell; fair amount of matter in suspension.

EFFLUENT, COARSE CONTACT BED.—Two hours' contact.

Oxygen absorbed, 15 mins.	1·66 grains per gallon
„ „ 4 hours	3·32 „ „
Chlorine	8·0 „ „
Ammonia, free	64·08 parts per million
„ Albuminoid	9·11 „ „
Appearance	Opaque; offensive smell.

EFFLUENT, FINE CONTACT BED.—Two hours' contact.

Oxygen absorbed, 15 mins.	0·20 grains per gallon.
„ „ 4 hours	0·43 „ „
Chlorine	8·0 „ „
Ammonia, free	43·77 parts per million.
„ Albuminoid	1·60 „ „
Appearance	Faint smell; large amount of suspended matter for an effluent.

EFFLUENT, EXPERIMENTAL.—THIRD CONTACT BED.

Chlorine	4·1 grains per gallon.
Ammonia, free	0·07 parts per million.
„ Albuminoid	0·19 „ „
Appearance	Bright and clear; free from smell.

EFFLUENT. FINAL FROM LAND.

Oxygen absorbed, 15 mins.	0·27 grains per gallon.
„ „ 4 hours	0·65 „ „
Chlorine	6·9 „ „
Ammonia, free	32·14 parts per million.
„ Albuminoid	1·30 „ „
Appearance	Opaque; large amount of suspended matter for an effluent. Large trace of ferrous iron in suspended matter.

Yours faithfully,
(Signed) JOHN E. FARMER,
Analyst.

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(15) Give a typical analysis of the crude sewage to which the experiment relates.	It may be explained here that exactly one-half of the dry weather flow is dealt with on bacteriological lines, the remaining portion being treated with chemicals, the solids pumped on to some land and ploughed in, whilst the top water is run through coke filters on the intermittent continuous process, and then run on to the land.
(16) Between what dates was the experiment conducted?	
If there were any periods of rest, state their duration.	
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	

Appendix 9C.

(18) Was any nuisance caused by the experimental works?	Complaints were received during the hot days in August last, relative to a smell arising from the scum on top of open septic tank, and it was deemed advisable to temporarily cover the same with tarpaulins which have since been removed.
(19) Is the experiment still proceeding? - - - If so, may the Commission inspect the works, should they deem it desirable to do so?	Certainly if the Commission deem the works worthy of a visit which should be shortly if they wish to see the open septic in use after over 300 days work, as the necessity of cleaning the tank out will have to be considered at no distant date as the depth of the solids at bottom, and the scum on the surface continues to increase, and it is now 50 per cent. of the cubical contents of the tank.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	That it is absolutely necessary to have an intercepting tank between the outfall and the primary or coarse beds, in order to intercept the silt and grease which otherwise would in a very short space of time cause the beds to lose a high percentage of their efficiency by the surface becoming clogged, which under present conditions of working seems to form one of the chief difficulties to be overcome in the bacteriological treatment of sewage without some form of precipitation being first undertaken.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	The dry weather flow is only considered in the undermentioned replies, as the conditions vary so much in respect to the wet weather flow in this town.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	About 1*l*. per head of the population.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	About 6*d*. per head, which should be still further reduced if the final treatment was by tertiary artificial beds, instead of land treatment. The foregoing approximate estimate does not allow for the periodical replacement of filtering media in the beds, but a sufficient area of artificial beds is included to allow for each filter being alternately rested until again fit for use.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Total organic nitrogen.

C. G. Mason, Borough Surveyor.
Signature of Officer under whose direction the experiment was conducted.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Heywood Corporation.
Population of district	26,000.
Water supply per head of the population	20 gallons per day.
Estimated or measured dry weather flow of sewage	800,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Partly from breweries and dye works. About 5 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	Sewage works manager.
Name and qualification of chemist who has made the analyses.	Joshua Bolton (advan.) S.K.
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	3,600.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Yes.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	After 6 months about 5-inch deposit on bottom of tank
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	42 per cent.
(*b*) What was the depth of these beds?	3 feet.
(*c*) What were the nature and size of the filtering material?	Passed 3-inch mesh; rejected by 1-inch mesh.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Measurement taken after 6 months working about $\frac{1}{3}$ capacity, no special period of rest given.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	About $\frac{1}{3}$.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material:	39 per cent.
(*b*) What was the depth of these beds?	3 feet.
(*c*) What were the nature and size of the filtering material?	Passed a 1-inch mesh; rejected by $\frac{1}{4}$-inch.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	Measurement taken after 6 months working, then about $\frac{1}{3}$ capacity, no special period of rest given.
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	34 per cent.
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	Taken under ordinary conditions, no special resting period.
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	$3\frac{1}{2}$ per 24 hours. $1\frac{1}{2}$ hours filling, 2 hours full. $\frac{1}{2}$ hour emptying and 3 hours resting
(10) State by what method the tank liquor was distributed on the beds.	Troughs.
(11) What was the average quantity of sewage in gallons dealt with daily?	220 gallons per square yard.

Appendix 9C.

(12) Was the quantity of sewage dealt with increased in time of storm?	Slightly.
If so, state to what extent, and how the results were affected by such increase.	Good results.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Daily. Bottle shaken.
(14) Give (*a*) the average of the analyses of the final effluent from the beds.	Oxygen absorbed in 4 hours - - - - - - 1·0 Chlorine - - - - - - - - - 5·9 Free ammonia - - - - - - - - ·60 Albuminoid ammonia - - - - - - - ·12 N as nitrites ·71. - - - - - - - ·71 N as nitrites not estimated.
(*b*) the best analysis of the final effluent and date when sample was taken, and	(*b*) September 28th, 1900. Oxygen absorbed 4 hours - - - - - - 0·32 Chlorine - - - - - - - - 2·90 Free ammonia - - - - - - - 0·28 Albuminoid ammonia - - - - - - - 0·07 Nitrates - - - - - - - - - 1·10
(*c*) the worst analysis of the final effluent and date when sample was taken.	(*c*) September 11th, 1900. Oxygen absorbed 4 hours - - - - - - 2·7 Chlorine - - - - - - - - 9·0 Free ammonia - - - - - - - 0·57 Albuminoid ammonia - - - - - - - 0·12 Nitrates trace.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	Not estimated.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Traces, non-putrescible.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	Average of many samples. Oxygen absorbed in 4 hours - - - - - 7·7 Chlorine - - - - - - - - - 5·9 Free ammonia - - - - - - - 2·10 Albuminoid ammonia - - - - - - - 0·51 Nitrates nil.
(16) Between what dates was the experiment conducted?	June 1st, 1900, to present date.
If there were any periods of rest, state their duration	1 day per week.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	Mean about 51° F.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - - -	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	Good results continuously. Only slight deposit on the beds, which have not been raked since experiments commenced.
(21) What inferences have been drawn from the experiment?	That the sewage of Heywood can be cheaply and effectively purified by the agency of bacteria, in open tanks and double contact beds.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	Not estimated.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	8*d*. per head.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

JOSHUA BOLTON.

Signature of Officer under whose direction the experiment was conducted.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS (DOUBLE CONTACT.)

Appendix 9C.

Name of authority	Huddersfield Corporation.
Population of district	105,000.
Water supply per head of the population	14 for domestic purposes, 9 for trade purposes } gallons per day.
Estimated or measured dry weather flow of sewage	Measured 7,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes, a large quantity, chiefly from the scouring, dyeing and finishing of wool, &c.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	29 per cent. of dry weather flow.
Is the storm, soil or surface water, wholly or partially excluded from the ordinary sewers?	A large quantity of storm and surface water enters the sewers.
Officer under whom the experiment has been conducted	Borough Engineer.
Name and qualification of chemist who has made the analyses.	Percy Coward.

(1) (*a*) What is the capacity in gallons of the open septic tanks or tank?

One tank, [illegible]5,000 gallons capacity.

(*b*) If there was more than one tank, state whether they were worked in series or in parallel.

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

Yes.

If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.

No sludge has as yet been removed from the septic tank. The tank was put into operation on 23rd July 1900, and on 7th January 1900 its condition was as follows:

	Ft.	in.
Depth of clear liquid	4	3
Depth of sludge (at foot)	1	3
Total depth	5	6

(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

3,987 gallons.

(*b*) What was the depth of these beds?

3 ft. 9 in.

(*c*) What were the nature and size of the filtering material?

Top 3 in., clinker $\frac{3}{16}$ in. to $\frac{1}{2}$ in.
Top 3 ft. 6 in., clinker 1 in. to 3 in.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Date.	Capacity.	Previous Rest.
	Gallons.	
22nd August 1900	3,987	Initial capacity.
24th September 1900	2,956	3 hours.
13th November 1900	2,730	3 "
14th January 1901	2,520	3 "

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?

The experiment is still proceeding.

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

After the coarse and fine beds had been in operation a few days, the contents of the coarse filled the fine so as to leave about $\frac{1}{2}$ in. of liquid above the material of the bed. Initial capacity, therefore, about 3,900 gallons.

(*b*) What was the depth of these beds?

3 ft. 9 in.

(*c*) What were the nature and size of the filtering material?

Top layer 3 in., clinker $\frac{3}{16}$ in. to $\frac{1}{2}$ in.
" 3·6 in. " $\frac{3}{16}$ in. to 1 in.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

None made.

Appendix 9C.

(8) (a) What was the water-holding capacity of fine beds at end of experiment?

Experiment still proceeding.

(b) Was this measurement made after resting, and, if so, what was the duration of the resting?

Experiment still proceeding.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.

Filled three times per day.

—	Coarse Bed.	Fine Bed.
(a) - - - - -	3 hours	3 hours.
(b) - - - - -	7 "	6 "
(c) - - - - -	3 "	3 "
(e) - - - - -	9 "	12 "

(10) State by what method the tank liquor was distributed on the beds.

It is not distributed on the beds, but allowed to flow on at one point.

(11) What was the average quantity of sewage in gallons dealt with daily?

Tank - - 55,000 gallons per day.
Beds - - 7,100 " "

(12) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase.

Not increased.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Samples are analysed daily. Neither filtered through paper nor allowed to settle before being analysed.

(14) Give (a) the average of the analyses of the final effluent from the beds.

Nitrous and nitric nitrogen -	·043	(8 weeks' average).
Ammoniacal nitrogen - -	·55	(19 " "
Albuminoid nitrogen - -	·123	(19 " "
Oxygen absorbed in four hours at 80° Fahr. - - - -	1·97	(19 " "
Oxygen absorbed in three minutes - - - -	·77	(19 " "

(b) the best analysis of the final effluent and date when sample was taken, and

(c) the worst analysis of the final effluent and date when sample was taken.

—	(b) 31st Dec. 1900.	(c) 21st Sept. 1900.
Ammoniacal nitrogen - -	·73	·09
Albuminoid nitrogen - -	·196	·046
Oxygen absorbed in four hours at 80° Fahr. - -	3·86	·69
Oxygen absorbed in three minutes - - - -	1·46	·21

(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.

Solids suspended:

Mineral - -	3·4
Volatile - -	6·6
Total - -	10·0

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Only traces present.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Nitrous and nitric nitrogen - - - -	·031
Ammoniacal nitrogen - - - - -	1·02
Albuminoid nitrogen - - - - - -	·459
Oxygen absorbed in four hours at 80° Fahr.:	
Sample shaken - - - - - - -	9·20
" settled - - - - - - -	7·09
Oxygen absorbed in three minutes - -	3·01

Reaction—Slightly alkaline to litmus.

Solids:

In suspension:	
Mineral - -	9·3
Volatile - -	20·3
Total - -	29·6
In solution:	
Mineral - -	58·2
Volatile - -	12·2
Total - -	70·4
Total solids:	
Mineral - -	67·5
Volatile - -	32·5
Total - -	100·0

(16) Between what dates was the experiment conducted?

Experiment commenced August 24th, 1900, and still being conducted.

If there were any periods of rest, state their duration.

The tank works continuously. The beds rest on Sundays. Both the tank and the beds rested one week in October 1900.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.

No observations have been made.

(18) Was any nuisance caused by the experimental works?

No.

(19) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Yes.

(20) Give particulars of any other observations of importance which were recorded.

As yet no permanent scum has formed upon the surface of the septic tank, the wind and rain beating the sludge, which is buoyed to the surface by the gas evolved, down again. An energetic action, however, takes place even in the coldest weather.

It has been noticed that the amount of solid matter in suspension increased as the septic action became more energetic, as the following results show:

—	Suspended Solids in Septic Effluent.		
	Mineral.	Volatile.	Total.
Average for the 2 weeks ended 5th Sept. 1900	1·4	5·2	6·6
4 ,, ,, 3rd Oct. ,,	2·9	5·3	8·2
4 ,, ,, 31st Oct. ,,	3·8	7·5	11·3
4 ,, ,, 28th Nov. ,,	4·3	7·9	12·2
4 ,, ,, 26th Dec. ,,	4·6	7·1	11·7

(21) What inferences have been drawn from the experiment?

Before any definite opinion can be formed of the open septic tank and double contact system, it will be necessary to have further experience, as it has, with the exception of the first few weeks at the commencement of the trial, been limited to the cold and wet months.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state.

Practicable to adopt the system.

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

1*l*. 15*s*. 5*d*.

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

6*s*. 7*d*.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

J. L. Campbell, M.Inst. C.E.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

(Southern Outfall. Coke-bed fed with sewage which had been passed through an open septic tank.)

Name of authority	London County Council.
Population of district	1,678,104 (1896). (Sewage derived from London South of Thames.)
Water supply per head of the population	34·8 gallons per day (1900).
Estimated or measured dry weather flow of sewage	About 90,000,000 gallons per day.
Is any trade refuse taken into the sewers?	All the trade refuse from the districts drained is taken into the sewers.
If so, state from what processes it is derived, and approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	The quantity of trade refuse is not known.
Is the storm, soil or surface water, wholly or partially excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted.	Dr. Clowes.
Name and qualification of chemist who has made the analyses.	Mr. J. W. H. Biggs.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	9,000.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	Only one tank.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Yes.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	The sludge has not been removed. After about five months work the liquid was drained off. The tank then contained 19 inches of sludge, containing 87·8 per cent. of moisture. The dried sludge contained 68 per cent. of inorganic matter, not removable by ignition in air. 67·1 per cent. of the suspended putrescible matter in the sewage was liquefied by septic action.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	2,750 gallons.
(*b*) What was the depth of these beds?	6 feet
(*c*) What were the nature and size of the filtering material?	Coke which passed through a 2-inch mesh, and which was rejected by a 1-inch mesh.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	(see table below)

Date.	Gallons.	Remarks.
5 Nov. 1900	2,750	An old coke-bed was used which had been working only four days with the septic effluent.
6 Dec. „	2,550	
9 Jan. 1901	2,150	
21 Jan. „	2,100	
7 March „	2,600	The bed had been resting from January 22nd.
1 May „	2,475	
12 June „	2,300	
21 Aug. „	2,200	
5 Oct. „	2,175	

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	2,175 gallons. After about one day's rest.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No fine beds were used.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	

Appendix 9C.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

Normally, four fillings per day. (*a*) $\frac{1}{2}$ hour filling; (*b*) 2 hours standing full; (*c*) 1 hour emptying, $2\frac{1}{2}$ hours resting. When the full number of fillings was impossible the resting periods were correspondingly increased.

(10) State by what method the tank liquor was distributed on the beds.

By splashing from distributing pipes upon perforated wooden trays.

(11) What was the average quantity of sewage in gallons dealt with daily?

While four fillings per day were made, 43,200 gallons passed through the septic tank in 24 hours. But 36,000 gallons represents the average flow, owing to the reduced number of fillings during part of the period.

(12) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase.

The experimental plant was not affected by storm water.

(13) State at what intervals analyses of the final effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Samples taken every $\frac{1}{4}$ hour, and average daily sample taken for analysis. The sample was filtered for all estimations except in the case of the estimations of oxygen absorbed by the total solids.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

—	No. 1 Bed.	No. 2 Bed.
Oxygen absorbed from permanganate in four hours at 80° F.:		
By the total putrescible matter.	2·445	2·456
By the dissolved putrescible matter.	1·850	1·765
Nitrous nitrogen - - -	0·0757	0·0740
Nitric nitrogen - - - -	0·0492	0·0703

(*b*) the best analysis of the final effluent and date when sample was taken; and

31st December 1900.

(*c*) the worst analysis of the final effluent and date when sample was taken.

16th January 1901.

—	(*b*)	(*c*)
Oxygen absorbed from permanganate in four hours at 80° F.:		
By the total putrescible matter.	1·474	5·876
By the dissolved putrescible matter.	1·158	5·051
Nitrous nitrogen - - -	0·250	0·044
Nitric nitrogen - - - -	0·137	0·077
Albuminoid nitrogen - -	0·154	0·410

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

13·6 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Suspended solids were not estimated. The final effluent was not putrescible in an incubator at 80° F.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Average for the whole period, 5th November 1900—4th October 1901:—

Oxygen absorbed from permanganate in four hours at 80° F	
By the total putrescible matter - -	5·936
By the dissolved putrescible matter - -	4·088
Nitrous nitrogen - - - - - - -	0·0005
Nitric nitrogen - - - - - - -	Nil.
Suspended solids - - - - - - -	26·5

(16) Between what dates was the experiment conducted?

5th November 1900—4th October 1901.

If there were any periods of rest, state their duration

Septic tank, Sundays; 27 other days at various times.
Coke-beds, Sundays; 11 other days at various times.

Appendix 9C.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	Not taken
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - - -	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	This system appears perfectly practicable, and a non-putrescible effluent of satisfactory character would b obtained by its adoption. A somewhat heavy expenditure would be incurred by pumping the effluen into the river during high water.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

FRANK CLOWES,
Chief Chemist to the London County Council.
Signature of Officer under whose direction the experiment was conducted.

Form B

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Beds A. and B. working in conjunction.

Name of authority	Manchester.
Population of district	550,000.
Water supply per head of the population	28 gallons per day : domestic, 17, trade, 11.
Estimated or measured dry weather flow of sewage	27,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Breweries, dye and bleach works, galvanising works, grease refineries, tanneries, manufactories of tar products, rubber goods works, tripe-dressing works, and mineral water manufactories. 4 to 5 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1. In certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc., F.I.C., Superintendent Chemist. W. Clifford, A.R.C. Sc.I. (Nov. 1898—Nov. 1899.) E. Ardern, B.Sc. (Vict.) (Nov. 1899.) H. D. Bell, A. Oddie, E. Hadfield, } Junior Assistants.
Name and qualification of chemist who has made the analyses.	Under direction of G. J. Fowler.

(1) (a) What is the capacity in gallons of the open septic tank or tanks.

,125,000.

(b) If there was more than one tank, state whether they were worked in series or in parallel.

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.

(3) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

(b) What was the depth of these beds?

3 feet.

(c) What was the nature and size of the filtering material?

Bed A.—Screened clinker. Rough material round the drain pipes, otherwise material uniform round the bed, which has passed 3-inch mesh, and rejected by 1-inch.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Date.	Capacity in Gallons.	Remarks.
13th April 1899	3,020	After 3½ hours rest.
20th ,, ,,	3,350	,, ,,

What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and if so, what was the duration of the resting?

(6) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(b) What was the depth of these beds?

3 feet.

(c) What was the nature and size of the filterin material?

Bed B. Screened clinker. Rough clinker round the drain pipes. Otherwise material uniform throughout the bed. Passed 1-inch mesh, rejected by ¼-inch.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not

Date.	Capacity in Gallons.	Remarks.
13th April 1899	4,000	2½ hours draining.
20th ,, ,,	4,350	,,

Appendix 9C.

Question	Answer
(8) (a) What was the water-holding capacity of fine beds at end of experiment?	
(b) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.	During this period the beds were filled 4 times each day, Sundays excepted. Cycle: (a) ¼ hour; (b) 2 hours; (c) ¼ hour; (e) 3½ hours. The contents of Bed A being, in each case, run on to Bed B.
(10) State by what method the tank liquor was distributed on the beds.	By means of wooden shoots, laid on the surface of the bed, perforated at the bottom of the sides.
(11) What was the average quantity of sewage in gallons dealt with daily?	11,550 (allowing for Sunday's rest).
(12) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Daily, except Sundays. Samples shaken before analysis.
(14) Give (a) the average of the analyses of the final effluent from the beds.	The following numbers are the average of daily analyses of final effluent (B).

Four Hours' Oxygen Absorption.	Incubator Test. 3 mins. Oxygen Absorption.		Putresci-bility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
	Before.	After.						
1·71	·67	·74	21/62	1·25	·13	·008	·189	15·0

Question	Answer
(b) the best analysis of the final effluent and date when sample was taken; and	
(c) the worst analysis of the final effluent and date when sample was taken;	
(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;	
(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Slight.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	The average of daily analyses of Settled Sewage during the month of May 1899 is as follows: 4 hours' oxygen absorption - - - 5·99 3 minutes' oxygen absorption - - - 3·37 Ammoniacal nitrogen - - - - 2·33 Albuminoid nitrogen - - - - ·324 Chlorine - - - - - - - - 16·0
(16) Between what dates was the experiment conducted?	27th April and 26th May, 1899.
If there were any periods of rest, state their duration.	Rested on Sundays, no other rest.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	
If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(20) Give particulars of any other observations of importance which were recorded.	Most of the unsatisfactory results obtained occurred during the first fortnight, the later results being much more satisfactory.

(21) What inferences have been drawn from the experiment?	The above observations would point to the fact that a bed which is accustomed to receiving settled sewage will not satisfactorily purify septic tank effluent without some period being allowed for its adjustment to the altered conditions. It is important, therefore, that beds should not be used indiscriminately for fresh or septicised sewage.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal —excluding the cost of land and cost of sewers;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system --excluding the annual repayment of any loan.	

Appendix 9C

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANKS AND CONTACT BEDS.

Beds C and D working in conjunction.

Name of authority - - - - - - - -	Manchester.
Population of district - - - - - - -	
Water supply per head of the population - - -	
Estimated or measured dry weather flow of sewage -	
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses.	

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?

1,125,000.

(*b*) If there was more than one tank, state whether they were worked in series or in parallel.

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.

(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

(*b*) What was the depth of these beds?

3 feet.

(*c*) What was the nature and size of the filtering material?

Bed C. Screened clinker. Rough material round the pipes. Material uniform throughout the beds. Passed $\frac{3}{4}$-inch, rejected by $\frac{1}{4}$-inch mesh.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Date.	Capacity in Gallons.	Remarks.
5th July, 1899	3,690	4 hours rest
17th August, "	3,250	4 "

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds?

3 feet.

(*c*) What was the nature and size of the filtering material?

Screened clinker. Rough material round the drainage pipes, otherwise uniform throughout the bed Passed $\frac{1}{2}$-inch mesh, and rejected by $\frac{1}{8}$-inch.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*), emptying, and (*e*) resting.

Date.	No. of fillings per day.	Time of filling.
June 1st to 7th - -	2	
June 8th to July 5th -	3	
July 5th to Aug. 16th	4	

Cycle in general: (*a*) $\frac{1}{4}$, (*b*) 2 hours, (*c*) $\frac{1}{2}$, (*e*) remainder of time according to the number of fillings, the contents of Bed C being in each case run on to Bed D.

Appendix 91'.

(10) State by what method the tank liquor was distributed on the beds.	By means of wooden shoots laid on the bed, perforated at the bottom of the sides.
(11) What was the average quantity of sewage in gallons dealt with daily?	10,510 gallons per day (allowing for Sunday's rest).
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Daily except Sundays. Samples shaken before analysis.
(14) Give (*a*) the average of the analyses of the final effluent from the beds;	The following numbers are the average of daily analyses of the final filtrate (from Bed D) for the periods given:—

Date.	Four Hours' Oxygen Absorption.	Incubator Test—3 min. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
		Before.	After.						
1899.									
Jan. 1—7 - - - - (2 fillings per day.)	·74	·27	·23	0—12	·40	·07	·088	·617	14·0
June 8—July 6 - - (3 fillings per day.)	·71	·33	·23	0—71	·39	·067	·081	·614	16·1
July 6—August 16 - (4 fillings per day.)	·71	·36	·29	0—54	·44	·054	·071	·728	15·7

(*b*) the best analysis of the final effluent and date when sample was taken; and (*c*) the worst analysis of the final effluent and date when sample was taken. (*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed. (*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Practically nil.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	The following numbers are the average of daily analyses of settled sewage from June 2nd to August 16th, 1899: 4 hours oxygen absorption - - - - - 6.54 3 minutes „ - - - - - 3·80 Ammoniacal nitrogen - - - - - 2·47 Albuminoid nitrogen - - - - - ·37 Chlorine - - - - - - - - - 16·1
(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	June 1st to August 17th, 1899. Rested on Sundays, no other rest.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	The chemical efficiency of the bed appears to increase as time goes on, the results from four fillings per day being even better than the earlier results with two fillings.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state (*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers; (*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Total organic nitrogen.

GILBERT J. FOWLER,
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Bed A (Single Contact).

Name of authority	Manchester.
Population of district	
Water supply per head of the population	
Estimated or measured dry weather flow of sewage	
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses.	

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	1,125,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	
Were any observations made as to the filling up of the septic tanks by deposit of sludge?	
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	3 feet.
(*c*) What was the nature and size of the filtering material?	Bed A. (after replacement).—Screened clinker. Rough clinker round the drainage pipes. 2 ft. 9 in. passed $\frac{3}{4}$-in. mesh, and rejected by $\frac{1}{8}$-in. 3 inches at top of fine material.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	See table below.

BED A.

Date.	Capacity in Gallons.	Remarks.
31st Aug. 1899	4,200	Bed A opened up on 2nd June and material taken out and broken down; exposed for two months. Replaced on 22nd August, and worked with 2 fillings per day. Measurement made after 4 hours' rest.
20th Sept. "	3,930	After 4 hours' draining.

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What was the nature and size of the filtering material?	

Appendix 9C.

( ) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	See table below.

Date.	No. of Fillings per Day.	Time of Filling.
26th—31st August 1899	2	12.15 p.m. and 6 p.m.
1st—13th Sept. ,,	3	6.30 a.m., 12.30 p.m., and 6.30 p.m.
Cycle: (*a*) ¼ hr., (*b*) 2 hrs.	(*c*) ¼ hr.	(*e*) Remainder of time, according to the number of fillings.

(10) State by what method the tank liquor was distributed on the beds.	By means of wooden shoots, perforated at the bottom of the sides.
(11) What was the average quantity of sewage in gallons dealt with daily?	9,500 gallons (allowing for Sunday's rest).
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Daily, except Sundays. Samples shaken before analysis.
(14) Give (*a*) the average of the analyses of the final effluent from the beds.	The following numbers are the average of daily analyses of the filtrate from Bed A for the periods given:—

Date.	Four Hours' Oxygen Absorption.	Incubator Test, 3 min. Oxygen Absorption. Before.	Incubator Test, 3 min. Oxygen Absorption. After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
23rd—31st August (2 fillings per day.)	2·48	1·37	1·43	1·5	1·17	·09	·176	* ·576	14·1
1st—13th September (3 fillings per day.)	2·28	1·11	1·03	3·11	1·27	·135	·034	·107	15·4

* High nitrate number for this period due to the fact that the bed had been resting for some time prior to this experiment.

(*b*) the best analysis of the final effluent and date when sample was taken, and	
(*c*) the worst analysis of the final effluent and date when sample was taken.	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Small amount.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	The following numbers are the average of daily analyses of *Settled Sewage* from 17th August—13th September, 1898:—

4 hrs. oxygen absorption - -	6·43
3 min. ,, ,, - -	3·64
Ammoniacal nitrogen - -	2·28
Albuminoid ,, -	·294
Chlorine - - -	16·0

Appendix 9C.

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	26th August—13th September 1899. Bed rested on Sundays.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - - If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Bed C (primary) worked in conjunction with Beds B and D (secondary).

Name of authority	Manchester.
Population of district	
Water supply per head of the population	
Estimated or measured dry weather flow of sewage	
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted.	
Name and qualification of chemist who has made the analyses.	
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	1,125,000.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel?	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(*b*) What was the depth of this bed?	3 feet.
(*c*) What was the nature and size of the filtering material?	Bed C.—Screened clinker. Except rough clinker round the drainage pipes, material uniform throughout the bed: to pass ¾ in. mesh and rejected by ¼ in.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of primary bed, stating in each case whether the measurement was made after resting or not.	(see table below)

Date.	Capacity in Gallons.	Remarks.
1899.		
August 17th	3,250	After 4 hours rest.
September 14th	1,965	„ 1¼ „
„ 15th	2,220	„ 3½ „

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	3 feet.
(*c*) What was the nature and size of the filtering material?	Bed B.—Screened clinker; to pass 1 in. mesh and rejected by ¼ in. Bed D.—Screened clinker; to pass ½ in. mesh and rejected by ⅛ in. In each rough clinker placed round the drainage pipes.
(7) Give particulars of measurements made from time to time during the experiments of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	(see table below)

Bed B.

Date.	Capacity in Gallons.	Remarks.
6 September 1899	3,680	After 7 days rest.
„ „	3,050	„ 1¼ hours draining.

Appendix 9C.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

Eight fillings per day on Bed C, four of which were run to B bed and four on to Bed D. Cycle for primary bed—(*a*) ¼ hour, (*b*) 1 hour, (*c*) ½ hour, (*e*) 1¼ hour. Cycle for secondary beds—(*a*) ½ hour, (*b*) 2 hours, (*c*) ½ hour, (*e*) 3 hours.

(10) State by what method the tank liquor was distributed on the beds.

By means of wooden shoots (perforated at the bottom of sides) laid on the surface of the beds.

(11) What was the average quantity of sewage in gallons dealt with daily?

33,600 gallons per day, after allowing for Sunday's rest.

(12) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

The following numbers are the average of daily analyses of the final filtrate—(*a*) from bed B, (*b*) from bed D:—

—	Four Hours' Oxygen Absorption.	Incubator Test—3 min. Oxygen Absorption. Before.	Incubator Test—3 min. Oxygen Absorption. After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
(*a*) Bed B filtrate -	·88	·41	·34	0—24	·78	·066	·039	·713	15·5
(*b*) Bed D filtrate -	·66	·31	·25	0—24	·39	·049	·034	·93	15·6

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.

(*e*) the average of the estimations made of the solids in suspension in the final effluent Were these putrescible?

Practically nil.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of *Settled Sewage* from August 17th to September 13th, 1899:—

4 hours oxygen absorption - -	6·43
3 mins. ,, ,, - -	3·64
Ammoniacal nitrogen - - -	2·28
Albuminoid nitrogen - - -	·294
Chlorine - - - - -	16·0

(16) Between what dates was the experiment conducted?

August 17th—September 15th, 1899.

If there were any periods of rest, state their duration

Beds rested on Sundays only.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.

(18) Was any nuisance caused by the experimental works?

No.

(19) Is the experiment still proceeding?

No.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Appendix 9C.

(20) Give particulars of any other observations of importance which were recorded.

Although the purification effected was quite satisfactory, the capacity of the primary bed rapidly diminished. This loss of capacity was, however, largely recovered after a few weeks rest, viz. :

Date.	Capacity in Gallons.	Remarks.
September 26th -	3,520	After 11 days rest.
,, ,, -	3,200	,, 3½ hours draining.
October 4th - -	3,650	,, further rest of 8 days.
,, - -	3,320	,, 3½ hours draining.

(21) What inferences have been drawn from the experiment?

Eight fillings per day are evidently in excess of what the primary bed can take for a prolonged period. Should it be necessary, however, on a special occasion to work the bed to this extent, it does not appear that permanent injury will result.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

(b) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Beds A (primary) and B (secondary) in conjunction.

Name of authority - - - - - - - -	Manchester.
Population of district - - - - - - -	
Water supply per head of the population - - -	
Estimated or measured dry weather flow of sewage -	
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses?	

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks? — 1,125,000 gallons.

(*b*) If there was more than one tank, state whether they were worked in series or in parallel.

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.

(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

(*b*) What was the depth of this bed? - - - — 3 feet.

(*c*) What was the nature and size of the filtering material? — A Bed.—Screened clinker. Rough material round the drainage pipes, 2 ft. 9 in., to pass $\frac{3}{4}$ in. and rejected by $\frac{1}{8}$ in. mesh; 3 in. top layer of fine material.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of primary beds, stating in each case whether the measurement was made after resting or not.

Date.	Capacity in Gallons.	Remarks.
20th September 1899 -	3,930	After $4\frac{1}{2}$ hrs. draining.
21st „ „ -	3,520	„ $1\frac{1}{4}$ „ „

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?

(6) (*a*) What was the water-holding capacity at commencement of experiment of the secondary beds when filled with the filtering material?

(*b*) What was the depth of this bed? - - - — 3 feet.

(*c*) What was the nature and size of the filtering material? — Bed B.—Screened clinker. Except for rough clinker round the drainage pipes, material uniform throughout the bed. To pass 1 in. mesh, and rejected by $\frac{1}{4}$ in. mesh.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the secondary beds, stating in each case whether measurement was made after resting or not.

Date.	Capacity in Gallons.	Remarks.
22nd September 1899 -	4,470	After $3\frac{1}{2}$ hrs. draining.
25th „ „ -	4,480	, $3\frac{1}{2}$ „
5th October „ -	4,590	$3\frac{1}{2}$

Appendix 9C.

(8) (a) What was the water-holding capacity of fine beds at end of experiment?	
(b) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.	Bed A (primary) filled four times per day. Cycle: (a) $\frac{1}{4}$; (b) 2 hrs.; (c) $\frac{1}{2}$ hr.; (e) $3\frac{1}{4}$ hrs. Contents of Bed A in each case being run on to bed B, and operation repeated.
(10) State by what method the tank liquor was distributed on the beds.	By means of wooden shoots laid on the surface of the bed.
(11) What was the average quantity of sewage in gallons dealt with daily?	12·635 (allowing for Sunday's rest).
(12) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Daily, except Sundays. Samples shaken before analysis.
(14) Give (a) the average of the analyses of the final effluent from the beds.	The following numbers are the average of daily analyses of filtrate from the secondary bed B:—

Four Hours' Oxygen Absorption.	Incubator Test, 3 Min. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
	Before.	After.						
·76	·33	·27	0—17	·37	·048	·037	·951	14·0

(b) the best analysis of the final effluent and date when sample was taken, and	
(c) the worst analysis of the final effluent and date when sample was taken.	
(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	
(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Very small amount.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	The following numbers are the average of daily analyses of *Settled Sewage* from 16th September—14th October, 1899:— Four hrs. oxygen absorption - - 5·77 Three min. „ „ - - 2·94 Ammoniacal nitrate - - - - - 1·80 Albuminoid „ - - - - - ·276 Chlorine - - - - - - - 13·9
(16) Between what dates was the experiment conducted?	16th September—14th October (inclusive) 1899.
If there were any periods of rest, state their duration.	Beds rested on Sundays only.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works	No

Appendix 9C.

(19) Is the experiment still proceeding? - - -	No
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(20) Give particulars of any other observations of importance which were recorded.	In this experiment the filtrates from the primary bed were in every case non-putrefactive
(21) What inferences have been drawn from the experiment?	
(22 If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

orm B.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Bed B (Single contact).

Name of authority - - - - - -	Manchester.
Population of district - - - - - - -	
Water supply per head of the population - - -	
Estimated or measured dry weather flow of sewage - -	
Is any trade refuse taken into the sewers?	
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse?	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses.	

(1) (a) What is the capacity in gallons of the open septic tank or tanks? — 1,125,000 gallons.

(b) If there was more than one tank, state whether they were worked in series or in parallel.

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion.

(3) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material? — 3 feet.

(b) What was the depth of the bed?

(c) What was the nature and size of the filtering material? — Bed B.—Screened Clinker.—With the exception of rough material round the drain pipes, material uniform throughout the bed. To pass 1-inch mesh, and be rejected by $\frac{1}{4}$-inch mesh.

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of bed, stating in each case whether the measurement was made after resting or not.

Bed B.

Date.	Capacity in Gallons.	Remarks.
1899:		
5 October - -	4,590	$3\frac{1}{2}$ hours' draining.
7 November - -	3,730	$3\frac{1}{2}$ " "
8 December - -	3,510	$17\frac{1}{2}$ " "
	3,130	$\frac{3}{4}$ " "
	3,100	$\frac{3}{4}$ " "
1900:		
27 February - -	3,300	4 days' rest.
27 February - -	3,030	$1\frac{1}{2}$ hours' drain ng.

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?

Appendix 9C.

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds?

(*c*) What was the nature and size of the filtering material?

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

4 fillings per day, as follows:—
5th October–7th December 1899, 6 hour cycle: (*a*) $\frac{1}{4}$ hour; (*b*) 2 hours; (*c*) $\frac{1}{2}$ hour; (*e*) $3\frac{1}{4}$ hours.
7th December 1899–22nd February 1900, 3 short cycles and one long cycle: (*a*) $\frac{1}{4}$ hour; (*b*) 1 hour; (*c*) $\frac{1}{2}$ hour; (*e*) $\frac{3}{4}$ hour; (3 times); (*a*) $\frac{1}{4}$ hour; (*b*) 1 hour; (*c*) $\frac{1}{2}$ hour; (*e*) $14\frac{3}{4}$ hours.

(10) State by what method the tank liquor was distributed on the beds.

By means of wooden shoots laid on the surface of the bed.

(11) What was the average quantity of sewage in gallons dealt with daily?

12,100 (after allowing for periods of rest).

(12) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses of the filtrate from Bed B. during the two periods of work:—
i., 4 cycles of 6 hours; *ii.*, 4 cycles in 10 hours, and 14 hours' rest.

—	Four Hours' Oxygen Absorption.	Incubator Test. 3 mins'. Oxygen Absorption. Before.	After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
i. 5 Oct.–7 Dec. -	2·07	1·03	1·06	16–54	1·20	·105	·039	·187	15·1
i. 7 Dec.–22 Feb. -	1·59	·81	·63	$16\frac{1}{2}$–101	1·06	·082	·024	·447	14·6

(*b*) the best analysis of the final effluent and date when sample was taken; and

(*c*) the worst analysis of the final effluent and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Small amount.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of *Settled Sewage* for the 6 months ending 28th March 1900.

4 hours oxygen absorption - - - -	7·23
3 mins. oxygen absorption - - -	3·70
Ammoniacal nitrogen - - - - -	2·21
Albuminoid nitrogen - - - - -	·306
Chlorine - - - - - - -	16·1

Appendix 9C.

(16) Between what dates was the experiment conducted?	5th October 1899 to 22nd February 1900.
If there were any periods of rest, state their duration.	Beds rested on Sundays and on 8th December 1899.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	The experiment shews that the purification effected by the bed is equally good, whether the fillings are distrbiuted equally over the whole of the 24 hours, or whether all take place in a short time, thus allowing a correspondingly longer period of rest at one time. Thus it is evidently possible to increase the rate of working of a bed for a short time, provided it has an equivalent period of rest, without any detrimental effect. The measurements of capacity shew that it is not advisable to work a bed on four fillings per day for a long period of time, without intervals of rest of some duration.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state.	
(*a*) What would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nirrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Signature of Officer under whose direction
the experiment was conducted.

Appendix 9C. Form B

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Bed B (single contact).

Name of authority	Manchester.
Population of district	
Water supply per head of the population	
Estimated or measured dry weather flow of sewage	
Is any trade refuse taken into the sewers?	
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted	
Name and qualification of chemist who has made the analyses.	

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?

1,125,000 gallons.

(*b*) If there was more than one tank, state whether they were worked in series or in parallel?

(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?

If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.

(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

(*b*) What was the depth of this bed?

3 feet.

(*c*) What was the nature and size of the filtering material?

Bed B.

Screened Clinker:

With the exception of rough clinker round the drainage pipes, material uniform throughout the bed. To pass 1-inch and be rejected by ¼-inch mesh. On 13th July, the top 3 inches of material were removed and replaced by material formerly on Bed D. (To pass ½-inch and rejected by ⅛th-inch mesh).

(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of bed, stating in each case whether the measurement was made after resting or not.

Bed B.

Date.	Capacity in gallons.	Remarks.
1900.		
7 May - -	3,400	13 days rest (rain prior to measurement).
7 May - -	3,080	4½ hours draining.
14 June - -	3,620	7 days rest.
14 June - -	3,200	1¼ hour draining.
12 July - -	4,150	7 days rest.
12 July - -	3,510	1¼ hour draining.
2 Aug. - -	3,220	17 hours draining.
2 Aug. -	2,980	1¼ hour draining.
9 Aug. -	3,540	7 days rest (wet weather).
9 Aug. -	3,010	1¼ hour draining (rain in meantime).
6 Sept. -	3,680	7 days rest.
6 Sept. -	3,050	1¼ hours draining.
4 Oct. - -	3,520	7 days rest (very wet weather).
4 Oct. - -	2,810	1¼ hours draining (very wet weather).
31 Oct. - -	2,680	1¼ hour draining.
8 Nov. -	3,310	7 days rest.
8 Nov. -	2,780	1¼ hours draining.

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and if so, what was the duration of the resting

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds?

(*c*) What was the nature and size of the filtering material?

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether the measurement was made after resting or not

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

1900, May 8th–June 6th.—2 fillings per day. Cycles: (*a*) $\frac{1}{2}$ hour, (*b*) $\frac{3}{4}$ hour, (*c*) $\frac{1}{2}$ hour, (*e*) $\frac{3}{4}$ hours; (*a*) $\frac{1}{2}$ hour, (*b*) $\frac{3}{4}$ hour, (*c*) $\frac{1}{2}$ hour, (*e*) $19\frac{3}{4}$ hours.
1900, June 13th–December 26th.—3 fillings per day. Cycles: (*a*) $\frac{1}{2}$ hour, (*b*) $\frac{3}{4}$ hour, (*c*) $\frac{1}{2}$ hour, (*e*) $\frac{3}{4}$ hour; (*a*) $\frac{1}{2}$ hour, (*b*) $\frac{3}{4}$ hour, (*c*) $\frac{1}{2}$ hour, (*e*) $\frac{3}{4}$ hour; (*a*) $\frac{1}{2}$ hour, (*b*) $\frac{3}{4}$ hour, (*c*) $\frac{1}{2}$ hour, (*e*) $17\frac{1}{4}$ hours.

(10) State by what method the tank liquor was distributed on the beds.

By means of shallow grips cut in the surface of the bed.

(11) What was the average quantity of sewage in gallons dealt with daily?

7,000 (allowing for all periods of rest).

(12) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses of filtrate from Bed B. for the two periods given:—

Date.	Four Hours' Oxygen Absorption.	Incubator Test. 3 mins. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
		Before.	After.						
1900. May 8th–June 6th (2 fillings per day).	3·16	1·77	1·45	5–37	1·20	·193	·089	·606	15·8
June 13th–Dec. 26th (3 fillings per day).	2·50	1·33	1·17	$27\frac{1}{2}$–124	1·13	·176	·035	·494	15·8

(*b*) the best analysis of the final effluent and date when sample was taken; and

(*c*) the worst analysis of the final effluent and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

Average of 75 determinations from August 2nd, 1900–January 24th, 1901 = 16·0 parts per 100,000.

Maximum - - - 27·1 parts per 100,000.
Minimum - - - 4·6 „ „

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Small amount.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of crude sewage for the half-year ending December 26th:—

4 hours oxygen absorption - - - -	11·11
3 minutes oxygen absorption - - - -	5·49
Ammoniacal nitrogen - - -	2·23
Albuminoid nitrogen - - - -	·59
Chlorine - - - - - - - -	17·0

(16) Between what dates was the experiment conducted?

Commenced May 8th, 1900, still proceeding. Results given up to December 26th, 1900.

If there were any periods of rest, state their duration.

Bed B rested on Sundays, and in general one week in four. Total rest = 80 days.

Appendix IIC

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	It is noticeable that the efficiency of purification increased as time went on. During the quarter ending 26th December, 1900, practically all the samples were non-putrefactive. It must be remarked that the open septic tank was restarted about the commencement of this experiment, the bed thus receiving practically fresh sewage for the first two months or so, as the septic action had not attained its full development. When this was attained, the purity of the filtrate increased.
(21) What inferences have been drawn from the experiment?	With thoroughly septicised effluent it is possible to purify to an adequate extent 534,000 gallons per acre per day, on beds 3 feet deep, without loss of capacity.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Form B.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS.

Beds A and C (primary) worked in conjunction with bed D (secondary)

Name of authority - - - - - - - -	Manchester.
Population of district - - - - - - -	
Water supply per head of the population	
Estimated or measured dry weather flow of sewage- -	
Is any trade refuse taken into the sewers? - - -	
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted.	
Name and qualification of chemist who has made the analyses.	

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	1,125,000.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What was the water-holding capacity at commencement of experiment of the primary beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	3 feet.
(*c*) What was the nature and size of the filterin material?	Screened Clinker Bed A. Rough clinker round the drainage pipes, 2 feet 9-in. To pass $\frac{3}{4}$-in., and rejected by $\frac{1}{8}$-in., 3-in. top layer of fine material. Bed C. With exception of roug clinker round the pipes, material uniform throug out the bed. To pa $\frac{3}{4}$-in. mesh, and rejecte by $\frac{1}{4}$-in.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	

Bed A. Date.	Bed A. Capacity in Gallons.	Bed A. Remarks.	Bed C. Date.	Bed C. Capacity in Gallons.	Bed C. Remarks.
November 2nd, 1899	2,960	3 hours draining.	October 4th, 1899	3,320	$3\frac{1}{2}$ hours draining.

NOTE. The last two capacity measurements for beds A and C are given to shew the increase after prolonged rest. They are not included in subsequent calculations of work done.

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	

Appendix 9C.

(6) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(b) What was the depth of this bed?

At commencement 3 feet. Reduced to 2 feet by removal of top foot on March 22nd, 1900.

(c) What was the nature and size of the filtering material?

Bed D. Screened clinker. With the exception of rough clinker round the drainage pipes, material uniform throughout the bed. To pass $\frac{1}{2}$-in. and rejected by $\frac{1}{8}$-in. mesh.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not?

BED D.

Date.	Capacity in Gallons.	Remarks.
September 19th	3,410	After 1 hour's draining.
November [illegible]th	3,960	„ 1 day's rest.

(8) (a) What was the water-holding capacity of fine beds at end of experiment?

(b) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.

Four fillings per day each on the primary beds A and C, Cycle, (a) $\frac{1}{4}$ hour, (b) 2 hours, (c) $\frac{1}{2}$ hour, (e) $3\frac{1}{4}$ hours. Secondary bed D received the contents from each primary bed. Cycle, (a) $\frac{1}{2}$ hour, (b) 1 hour, (c) $\frac{1}{2}$ hour, (e) 1 hour.

(10) State by what method the tank liquor was distributed on the beds.

By means of wooden shoots laid on the surface of the beds; the shoots were perforated at the bottom of the sides.

(11) What was the average quantity of sewage in gallons dealt with daily?

15,180 gallons per day (allowing for all rests).

(12) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Daily except Sundays. Samples shaken before analysis.

(14) Give (a) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses of filtrates (*i.*) Primary Bed A, (*ii.*) Primary Bed C. and (*iii.*) Secondary Bed D.

	Four Hours Oxygen Absorption.	Incubator Test. 3 mins. Oxygen Absorption. Before.	After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
i. Filtrates from Bed A	2·01	10.1	·91	35—156	1·09	·101	·026	·27	15·3
ii. „ „ „ C	1·90	·89	·80	19—137	1·10	·104	·020	·285	15·4
iii. „ „ „ D	·67	·31	·23	0—293	·49	·041	·020	·838	15·0

(b) the best analysis of the final effluent and date when sample was taken; and

(c) the worst analysis of the final effluent and date when sample was taken;

(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Practically nil.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of *Settled Sewage* for the six months ending March 8th, 1900.

Four Hours Oxygen Absorption.	Three Minutes Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
7·20	3·70	2·12	·366	16·1

Appendix 9C.

(16) Between what dates was the experiment conducted?	October 5th, 1899-April 11th, 1900.
If there were any periods of rest, state their duration.	Beds rested on Sundays. Also Bed A from December 11th-14th, 1899 (inclusive) and Bed C from April 4th-11th, 1900 (inclusive).
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(20) Give particulars of any other observations of importance which were recorded.	On March 22nd the top foot of material from the secondary bed D was taken off. Owing partly, perhaps, to disturbance of the surface, an accumulation of fine material took place round the drainage pipes, thus impeding the drainage. On this account and also probably from the removal of the upper nitrifying layer, the bed at the end of the experiment ceased to give such satisfactory results, although all samples were non-putrefactive. The whole of the results are included in the average. Since this experiment the bed D has been opened, the drainage pipes put right, and the bed re-worked with as good results as ever. Attention may be drawn to the fact that the percentage reduction in capacity of the primary beds is considerably less than in a former experiment, when one primary bed was worked in conjunction with two secondary ones. The composition of the final filtrate obtained was practically identical in the two experiments. The above reduction in capacity was to a large extent recovered by a fortnight's rest in the early summer.
(21) What inferences have been drawn from the experiment?	It is evident from this and former experiments that it is not necessary to have an equal area of primary and secondary beds in order to produce a satisfactory filtrate. It is also clear that the reduction is made with the greatest advantage in the area of the secondary beds. The measurements of capacity shew that it is not advisable to work primary beds for a prolonged period of time on four fillings per day, without intervals of rest of some duration.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers,	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual payment of any loan.	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	

Appendix 9C.

(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds? - - - -

2 feet.

(*c*) What was the nature and size of the filtering material?

Bed D. Screened Clinker. With the exception of rough material round the drain pipes, material uniform throughout the bed. To pass ½-in. and rejected by ⅛-in. mesh.

(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

Bed D.

Date.	Capacity in Gallons.	Remarks.
1900.		
May 17th ...	2,380	2 hours draining.
September 10th	2,220	1 day's rest.
„ 17th	1,880	2½ hours draining.
„ 24th	2,530	8 days rest.
	2,570	15 days rest. (Wet weather).

(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?

(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

1900.—May 3rd to May 31st, 2 fillings per day.
(*a*) at 12 noon and 6 p.m.
(*c*) at 9 a.m. and 3 p.m.

1900.—June 1st to December 26th, 3 fillings per day.
(*a*) at 5 a.m., 1 p.m. and 9 p.m.
(*c*) at 9 a.m., 5 p.m. and 1 a.m.

Cycle, (*a*) ½ hour; (*b*) 1 hour; (*c*) ½ hour; (*e*) rest of time according to number of fillings.

The primary beds were given one week's rest in four. In each case the filtrates from Beds A and C are discharged on to beds and given an hour's contact.

(10) State by what method the tank liquor was distributed on the beds.

At commencement by means of wooden shoots laid on the surface of the bed.

On November 12th these shoots were removed in the case of the primary beds A. and C, and shallow grips cut in their place, in the surface of the bed.

(11) What was the average quantity of sewage in gallons dealt with daily?

9,000. (Allowing for all periods of rest).

(12) Was the quantity of sewage dealt with increased in time of storm?

An extra filling was occasionally put on the beds, at times of heavy flow, without any detrimental effect.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses of the filtrate from primary Beds A and C, and secondary Bed D for the two periods given:—

1900.	Beds.	Four Hours Oxygen Absorption.	Incubator Test—3 mins. Oxygen Absorption.		Putrecibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chorline.
			Before.	After.						
March 3—31 - -	A.	2·48	1·31	·94	1½-37	·70	·13	·06	1·08	15·8
(2 fillings per day)	C.	2·15	1·10	·64	1½-36	·72	·14	·06	1·28	15·4
	D. (final effluent)	·81	·34	·27	0-75	·55	·073	·033	1·43*	15·1

	D. (final filtrate)	·79	·34	·26	0-182	·235	·066	·027	1 04	15·4

* High nitrate numbers for this period, due largely to prolonged period of rest, just prior to the commencement of this experiment.

Appendix 9C.

(*b*) the best analysis of the final effluent and date when sample was taken ; and	
(*c*) the worst analysis of the final effluent and date when sample was taken ;	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed ;	Average of 75 determinations from August 2nd, 1900, to January 24th, 1901 = 16·0 parts per 100,000. Maximum - - - 27·1 parts per 100,000. Minimum - - - 4·6 " " "
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Practically nil. No.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	The following numbers are the average of daily analyses of *Crude Sewage* for the half-year ending December 26th, 1900 : 4 hours xoygen absorption - - - 11·11 3 minutes oxygen absorption - - - 5·49 Ammoniacal nitrogen - - - - 2·23 Albuminoid nitrogen - - - - - ·59 Chlorine - - - - - - - - 17·0
(16) Between what dates was the experiment conducted?	Commenced May 3rd, 1900, results given up to December 26th, 1900. Experiment proceeding.
If there were any periods of rest, state their duration.	Primary beds A and C given one week's rest in four. Beds A, C and D rested on Sundays. Total rests Beds A, and C = 91 days each. (Including Sundays) Bed D = 45 days.
(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - - -	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	Measurements of capacity of the primary beds made during this experiment shew that there was practically no reduction in capacity ; it must be borne in mind that during a considerable part of the experiment it was summer time. Recent measurements have shewn that during the winter months the capacity is not so well maintained, but it has never been so low as at the end of the period preceding this experiment. The surface of the beds required very little attention.
(21) What inferences have been drawn from the experiment?	Primary beds in Manchester may be safely worked on three fillings per day of septic tank effluent, with one week's rest in four, together with Sundays. Any decrease of capacity during the winter may probably be largely recovered by an extra week's rest in the summer. It is possible to effectively distribute the tank effluent on the beds by simply cutting shallow grips in the surface.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers?	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan?	

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

GILBERT J. FOWLER.
Signature of Officer under whose direction the experiment was conducted.

Form B. Appendix 9 C

GENERAL OBSERVATIONS.—MANCHESTER.

SLUDGE REMOVED FROM THE OPEN SEPTIC TANK.

The open septic tank was first emptied on April 26th, 1900; it had then been working almost exactly fourteen months, having been started on February 24th, 1899.

The average daily rate of flow during that time was approximately 2,000,000 gallons.

Besides the suspended matter contained in the ordinary sewage, several hundred barrow loads of garbage were tipped into the tank.

The amount of sludge remaining in the tank at the end of the above period of working amounted in bulk to 4,000 tons of 90 per cent. sludge, but as in this case only 84 per cent. of moisture was present the actual weight of sludge would be greater than the above figure.

It was concluded from the above experiment that from 50 to 60 per cent. of the sludge which would otherwise accumulate had disappeared.

No exact estimate of the amount of sludge actually destroyed was possible from the data available, and it should be noted that a considerable amount of suspended matter passed away in the tank effluent.

Recent more exact experiments have shown that with a tank space equal to half the daily flow of Manchester sewage, it is possible when the tank is in full working order to destroy about one-third of the total suspended matter in the sewage.

The percentage destruction is, however, much less during the earlier periods of working; it is important, therefore, when it is necessary to remove the sludge that this should be done, as far as possible, without interfering with the septic action.

A tank arranged for this purpose is in process of construction.

Character of the Septic Tank Effluent.

(i.) Experiment has shewn that the effluents from the closed and open septic tanks are practically identical in composition.

(ii.) The suspended matter in the septic tank effluent is of a granular character and readily separates out on standing, and when arrested on the surface of a bacteria bed does not seriously impede the free flow of the water into the bed.

(iii.) The organic matter in solution is much more easily nitrified than that at present in fresh sewage, so that it is possible with one contact to constantly obtain non-putrefactive filtrates; in the case of raw and settled sewage this is seldom the case.

(iv.) The blending which takes place in the septic tank is of value in minimising the effect of excessive amounts of manufacturing refuse, and in producing an effluent of fairly constant composition.

Capacity of Beds.

(i.) There is rapid initial decrease in the capacity of the beds; this is manifestly due in part to the consolidation of the material of the bed.

(ii.) After this initial decrease it has been found possible by allowing suitable periods of rests, to maintain a capacity equal to from 25 to 33 per cent. of the empty capacity of the bed for a considerable period of time. The capacity appears to be best maintained if it is never allowed to decrease below a certain limit before rest; frequent short periods of rest, say, of three days or a week, are better than long periods of the same total duration.

Recovery of capacity does not take place to an equal extent when the bed is rested during the winter months as is the case in the summer. It appears probable that any decrease in capacity in the winter, excluding the initial period above referred to, may be more than recovered during the summer.

Labour on the Beds.

During the earlier period of working very little labour is required and after two years raking the surface about once a month appears to be all that is necessary.

Method of working Beds.

It has been established beyond doubt that one secondary bed can safely receive the filtrate from two primary beds.

Distribution of tank effluent on the bed can be simply effected by means of shallow grips cut in the surface.

The primary beds may safely receive three fillings of septic tank effluent per day, when ten days rest in twenty-eight are allowed.

Four fillings a day can be effectively purified by the beds, but the capacity figures in this case show more rapid decrease. An occasional extra filling in time of storm can however be put upon the beds without any apparent detriment.

With regard to the cycle of operations, experiment has shown that the purification effected depends rather upon the amount of tank effluent dealt with per given area, than upon the length of cycle employed. Two short cycles and one long one in the twenty-four hours giving results equal to, if not better than three cycles of equal duration. Variations in the rate of flow can thus be dealt with and in cases of large increases of flow, the rate of working of the beds may be temporarily increased without subsequent ill effect.

It appears that the period of rest is of more consequence than the period of contact, and that in most cases it is not advantageous for the latter to exceed one hour.

Other things being equal it appears preferable to allow a bed a period of complete rest rather than simply to reduce the number of fillings as it has been found, after a rest say of a week, that nitrification continues exceptionally active for about ten days.

Appendix 9C.

COMPOSITION OF FILTRATE.

The filtrate obtained from bacteria beds dealing with septic tank effluent has been found to contain enough residual oxygen either in solution or in combination as nitrate to further oxidise any impurity still remaining or even to purify a certain proportion of less perfectly treated sewage. If abundance of air be also present this oxidation will be carried further.

GENERAL CONCLUSIONS.

The experiments have shown that by means of a septic tank and one contact bed, non-putrefactive filtrates may almost invariably be obtained; by providing one secondary bed to two primary beds a filtrate of exceptional purity may be obtained.

With careful working it appears possible to deal with the septic tank effluent on primary beds at the rate of 750,000 gallons per day; allowing, therefore, one secondary bed to two primary beds, a total area of 60 acres should be adequate to deal with an average flow of 30,000,000 gallons per day.

MAINTENANCE OF BEDS. RESTING PERIODS.

The choice of lengthened periods of rest will be conditioned by (i.) the state of the bed, (ii.) the weather, and (iii.) the season of the year, *e.g.*—

(i.) If a bed is working well, and its capacity appears to be maintaining itself, it would not be economical to interrupt its activity.

(ii.) If possible, necessary rests should be given when the weather is fine, dry and breezy.

(iii.) It will not be advisable to rest the beds for a lengthened period in very cold weather, as in the absence of the heat of the sewage, the bacterial activity is to a large extent inhibited. If it is necessary to rest under these conditions it should be done by reducing the number of fillings per day.

Judgment will be required to be exercised in all cases in considering the simultaneous effect of variations in the above conditions.

WORK UPON THE SURFACE OF THE BEDS.

At no time should the surface of a bed be allowed to become water-logged. If such a tendency manifests itself the bed should be rested, and the surface raked to not more than the depth of the upper layer. If raking is not adequate for the purpose it may be necessary to remove some of the top layer and pile it in heaps, possibly on the bed itself, for an indefinite length of time, to recover. This may be eventually put back in place of further clogged material.

QUESTION 22

(a). It has been concluded that a system of open septic tanks and contact beds may safely be recommended for the purification of the sewage of Manchester.

The capital cost, in addition to the cost of the present works, has been estimated at £347,700, or 12s. 8d. per head of population. This includes an area of 46 acres of primary beds at Davyhulme, connected by a conduit to 23 acres of secondary beds at Carrington, together with roadways, electrical equipment for working the sluices and lighting the works.

The estimate also includes provision of 25 acres of storm beds and a liberal allowance for sundries and contingencies.

The cost of present works, excluding purchase and under-drainage of land, is £165,500, or 6s. per head of population. It may be taken, therefore, that for a population of 550,000 the bacterial system may be applied at a total capital cost per head of 18s. 8d.

(b). This has been estimated at £20,000, or 9d. per head of population.

The estimate includes cost of working and maintaining the beds (raking, renewing surface, and washing once in 10 years), the disposal of residual sludge and general expenses of management.

GILBERT J. FOWLER,

March 6th, 1901

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (SINGLE CONTACT.)

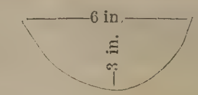
Name of authority - - - - - -	County Borough of St. Helens.
Population of district, estimated to June, 1901 - -	90,444.
Water supply per head of the population - -	Domestic supply 21 gallons per day. Domestic, including trade, 39 gallons per day.
Measured dry weather flow of sewage - -	2,000,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No, but there is drainage from chemical waste heaps after rain. Impossible to state proportion affected.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially excluded.
Officers under whom the experiment has been conducted	The Borough Engineer and the Medical Officer of Health.
Name and qualification of chemist who has made the analyses.	F. Drew Harris, M.B., London, M.R.C.S., D.P.H., Medical Officer of Health and Public Analyst for Borough.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	56,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	One only.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion.	Yes. Little or no sludge appears to be in the tank. It has not yet been emptied, having only been working four months.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Not ascertained. We have only two beds, each filled with similar filtering material.
(*b*) What was the depth of these beds?	3 ft.
(*c*) What were the nature and size of the filtering material?	2 ft. 10 in. coarse clinker held up by $\frac{1}{2}$ in. and 2 in. of siftings.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Not ascertained.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	Experiments are still going on.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	We have no fine beds.
(*b*) What was the depth of these beds? - - -	
(*c*) What were the nature and size of the filtering material?	
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	First bed filled 8 a.m.; stands full one hour; effluent distributed to second bed 9 a.m.; stands full one hour; each bed rests seven hours. Second filling takes place 4 p.m.; stands one hour; effluent distributed to second bed at 5 p.m.; stands one hour; beds rest till following morning at 8.

Appendix 9C.

(10) State by what method the tank liquor was distributed on the beds.

By means of 6 in. half-pipe channel laid across bed-



(11) What was the average quantity of sewage in gallons dealt with daily?

About 1,600 gallons each filling.

(12) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase.

No.

(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to settle before being analysed.

Effluent analysed twice daily, *i.e.*, from each filling.

Not filtered through paper or allowed to settle before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

Ammoniacal nitrogen, 0·62 per 100,000.

Albuminoid nitrogen, 0·10 per 100,000.

(*b*) the best analysis of the final effluent and date when sample was taken; and

5th January, 1901—Albuminoid nitrogen = 0·04 per 100,000.

(*c*) the worst analysis of the final effluent, and date when sample was taken;

6th November, 1900—Albuminoid nitrogen = ·22 per 100,000.

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

None made.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

None made. Effluent not putrescible.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Parts per 100,000:

Total solids	437·6
Ammoniacal nitrogen	2·3
Albuminoid nitrogen	0·9
Nitric nitrogen	0·0
Chlorine	148·3
Suspended matter	51·4

(16) Between what dates was the experiment conducted?

If there were any periods of rest, state their duration.

Commenced 3rd November, 1900, and is still proceeding.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.

None made.

(18) Was any nuisance caused by the experimental works?

No.

(19) Is the experiment still proceeding? - - - -

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

There is but little to see, but of course that little may be seen if desired.

(20) Give particulars of any other observations of importance which were recorded.

There is a marked improvement in the effluent from the final bed as compared with that from the first bed. This is evidenced by the great dimunition in the albuminoid nitrogen and the ammoniacal nitrogen found in the final effluent, and also by the presence in it of a quantity of nitric nitrogen which is entirely absent in the first.

(21) What inferences have been drawn from the experiment?

At present the purification is regarded as satisfactory, but further experience is necessary before making any inference.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

The point has not been considered.

(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

GEO. WM. BAILEY,
Town Clerk, St. Helens,

22nd February, 1901.

Signature of Officer of Committee under whose direction the experiment was conducted

Appendix

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS (DOUBLE TANK.)

Name of authority - - - - - - - -	Walsall.
Population of district - - - - - - - -	2,200 drain to these outfall works.
Water supply per head of the population - - -	20 gallons per day.
Estimated or measured dry weather flow of sewage -	78,240 gallons per day.
Is any trade refuse taken into the sewers? - - -	Yes, two small breweries.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	No. A quantity of storm and subsoil water finds its way into sewers, probably nearly 50 per cent.
Officer under whom the experiment has been conducted -	Borough Surveyor.
Name and qualification of chemist who has made the analyses.	F. E. Thompson, A.R.C.S.Lond., F.C.S.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	23,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	One.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge? If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion.	No sludge has been removed up to the present. N.B.—Previously this tank was used as a settling tank, and was always full in three months, but since being turned into a septic tank six months ago it has not been emptied, and soundings taken indicate the formation of practically no sludge.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	5,000 gallons.
(*b*) What was the depth of these beds? - - -	2 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Blast furnace slag broken to a 2-in. size.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No accurate observation taken, but they have lost about one-third of original capacity. After six months continuous working one of the beds was cleaned out, and there was found only a slight black sediment formed alongside of some of the underdrains.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and, if so, what was the duration of the resting?	No experiment.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Our fine beds each hold 5,000 gallons.
(*b*) What was the depth of these beds?	1 ft. 9 in. (material).
(*c*) What were the nature and size of the filtering material?	Blast-furnace slag passed through 1-in. and held on $\frac{1}{4}$-in. riddle.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	No experiments concluded.
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	No experiments concluded.
(*b*) Was this measurement made after resting, and, if so, what was the duration of the resting?	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	We have only four top and four bottom beds laid experimentally, and obtain two fillings per 24 hours. The time taken in filling varies according to the flow of sewage; the sewage is held in contact in coarse beds for four hours, the beds empty in about $1\frac{1}{2}$ hours, and never rest less than two hours. It is quite impossible to work the beds to any fixed hours, as the flow varies so much.
(10) State by what method the tank liquor was distributed on the beds.	Runs into a chamber, and then fills up gradually is not spread on surface at all.
(11) What was the average quantity of sewage in gallons dealt with daily?	30,000.

Appendix 9C.

(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.

All above the 300,000 gallons is turned on to land. When storm water has been dealt with very good results have been obtained.

(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper, or allowed to settle before being analysed.

Not filtered or allowed to stand, but were agitated before being analysed.

(14) Give (a) the average of the analyses of the final effluent from the beds;

Total solids dried at 212° Fahr.	= 99·3	parts per 100,000.
Ammoniacal nitrogen	= ·37	" "
Albuminoid nitrogen	= ·14	" "
Nitric nitrogen	= ·06	" "
Combined chlorine	= 9·90	" "
Oxygen absorbed at 80° Fahr.	= ·52	" "

(b) the best analysis of the final effluent, and date when sample was taken; and

(c) the worst analysis of the final effluent, and date when sample was taken;

Total Solids.	Ammoniacal NH_3.	Albuminoid NH_3.	Nitric NH_3.	Chlorine.	Oxygen absorbed.
77·4	·16	·08	·06	6·7	·39
				(31st December, 1900.)	
97·5	·60	·33	None.	9 3	·83
				(8th October, 1900.)	

(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed;

We take total solids.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

See above reply.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Total Solids.	Ammoniacal NH_3.	Albuminoid NH_3.	Nitric NH_3.	Chlorine.	Oxygen absorbed.
169·3	3·15	2·00	Trace.	9·0	7·44

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.

None taken.

(18) Was any nuisance caused by the experimental works?

No.

(19) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works should they deem it desirable to do so?

Yes.

(20) Give particulars of any other observations of importance which were recorded.

Occasionally the final effluent, on keeping for a few days, becomes of a brown colour, and a reddish brown deposit collects. A test is about to be made as to its composition.

Generally the effluents are found to improve on keeping.

Some nine months ago we started the bacteria beds with crude sewage, but they soon began to show signs of secondary decomposition through blocking.

About five weeks ago the beds were completely thrown out of condition owing to sufficient arsenical beer being run off (one night) to fill the whole of the beds once over with nothing but beer. They are now getting back after a rest.

(21) What inferences have been drawn from the experiment?

Our experience up to the present leads us to hope for satisfactory results.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—

Question will be decided later on.

(a) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;

(b) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

R. H. MIDDLETON, A.M.I.C.E.,
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

Form B.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Corporation of York.
Population of district	About 75,000.
Water supply per head of the population	33 gallons per day.
Estimated or measured dry weather flow of sewage	45 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Trade refuse is so small as to be negligible.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Storm water above the capacity of the sewers, yes. Soil or surface, no.
Officer under whom the experiment has been conducted	City Engineer.
Name and qualification of chemist who has made the analyses.	(*a*) Thomas Fairley, F.I.C., F.R.S. Edinburgh, F.C.S. London, &c. (*b*) Edmund Moody Smith, M.D., C.M., Edinburgh, D.P.H. Cambridge, Medical Officer of Health, York.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	250,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	One tank only.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	It is tested from time to time by a glass tube, but only a very slight deposit of about 2 inches has been found.
If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion.	The supernatant water was drawn off on 26th August, after 63 days use, when the sludge was found to average 2 inches over the whole area of tank; this was removed. No sludge has been removed since, and I cannot find more than 2 inches of sludge at date, though by the same means we can detect 6 inches of sludge in the adjoining tanks used for chemical precipitation.
(3) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	10,984.
(*b*) What was the depth of these beds?	3 feet 3 inches.
(*c*) What were the nature and size of the filtering material?	Clinker and coke, 3-8ths of an inch to 7-8ths of an inch.
(4) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	23rd November, 1900; 10,984, after $2\frac{1}{2}$ hours rest. 28th January, 1901; 8,648, after $2\frac{1}{2}$ hours rest.
(5) What was the water-holding capacity of the coarse beds at end of experiment? Was this measurement made after resting, and if so, what was the duration of the resting?	Experiment still in operation.
(6) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Not ascertained; the surface of this bed has remained clear of any deposit throughout.
(*b*) What was the depth of these beds?	3 feet 3 inches.
(*c*) What were the nature and size of the filtering material?	All rejected by a $1\frac{1}{4}$-inch screen.
(7) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	Not ascertained. The second or fine bed might have been smaller as it has not filled more than 2 feet in depth, when contents of coarse filter has been run into it, and on no occasion has there been any deposit on the surface or has forking over been necessary.
(8) (*a*) What was the water-holding capacity of fine beds at end of experiment?	
(*b*) Was this measurement made after resting, and if so, what was the duration of the resting?	

Appendix 9C.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying and (*e*) resting.	8 hour cycles. (*a*) $1\frac{1}{4}$ hours. (*b*) 2 hours. (*c* &) $4\frac{3}{4}$ hours.
(10) State by what method the tank liquor was distributed on the beds.	Semi-circular glazed drain pipes.
(11) What was the average quantity of sewage in gallons dealt with daily ?	From 30,000 to 32,000 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm ?	No.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to settle before being analysed.	Weekly. Samples not filtered, but allowed to clear before being analysed.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

(*a*)	
Total solids	63·51
Mineral matter	60·51
Volatile and organic matter	3·0
Free ammonia	0·438
Albuminoid ammonia	0·124
Nitrogen as calcium nitrate	2·55
Nitrogen as nitrites	nil
Oxygen required to oxidise organic matter in four hours.	0·897
Reaction	Alkaline
Chlorine	6·76
Sediment	trace
Analysts	Mr. Fairley and Dr. Smith.

(*b*) the best analysis of the final effluent and date when sample was taken, and—

(*c*) the worst analysis of the final effluent and date when sample was taken.

(*b* & *c*)	Best. 9 Jan. 1901.	Worst. 29 Nov. 1900.
Total solids	63·51	—
Mineral matter	60·51	—
Volatile and organic matter	3·0	—
Free ammonia	·886	·4
Albuminoid ammonia	·0957	·28
Nitrogen as calcium nitrate	·743	5·0
Nitrogen as nitrites	trace	—
Oxygen required to oxidise organic matter in four hours.	·514	·93
Reaction	Alkaline	—
Smell (when cold)	slight earthy	
Chlorine	6·76	—
Sediment	trace	—
Containing organic matter	—	—
Analyst	Mr. Fairley and Dr. Smith.	

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the first bed.	Not ascertained.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible ?	Trace only, *i.e.*, under 1 grain. No.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Total solids	96·43
Mineral matter	75·31
Volatile and organic matter	21·11
Free ammonia	4·0
Albuminoid ammonia	·943
Nitrogen as calcium nitrate	nil
Nitrogen as nitrites	nil
Oxygen required to oxidise organic matter in four hours.	3·43
Reaction	Alkaline
Smell (when cold)	very offensive
Chlorine	9·0
Sediment	28·84
Containing organic matter	25·28
Analyst	Mr. Fairley.

(16) Between what dates was the experiment conducted ? If there were any periods of rest, state their duration.	29th November, 1900, to date and containing only the periods in ordinary working.

Appendix 9C.

(17) Give particulars of any observations which have been made of the temperatures of the contact beds at different depths.

	Atmosphere.	No. 1 Bed.
29th November 1900 at 8 p.m.	42	47
1st December 1900 at 9 p.m.	42	47
3rd December 1900 at 9 a.m.	38	44
The lowest temperatures recorded from 29th November 1900 to 28th January 1901 were on 2nd January 1901 at 9 a.m.	28	40
2nd January 1901 at 9 p.m.	28	41
3rd January 1901 at 9 p.m.	28	41
9th January 1901 at 9.30 a.m.	23	40
16th January 1901 at 9 a.m.	27	41

We have daily temperatures of atmosphere in No. 1 Bacteria Bed from 19th December 1900 to date. These can be furnished if required; the above however are typical.

(18) Was any nuisance caused by the experimental works? — No.

(19) Is the experiment still proceeding? — Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so? — Yes.

(20) Give particulars of any other observations of importance which were recorded. — This experiment has only been in operation since November.

(21) What inferences have been drawn from the experiment? — The experiment with open septic effluent has been too short a time in operation to enable me to express an opinion. The results however are satisfactory, so far as they go.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

It is considered practicable to adopt this system, but in view of the superior results obtained by open septic tank treatment followed by continuous filtration (*see* Form G.) it is not considered expedient.

Note.—It is requested that all analyses may be given in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

This cannot now be done; the analyses are given as received. A standard form for sewage analyses is very much needed.

A. Creer.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT) AFTER CHEMICAL PRECIPITATION.

Name of authority	Batley Corporation.
Population of district	30,000.
Water supply per head of the population	For domestic purposes 12 gallons per day; for trade purposes 26 gallons per day.
Measured dry weather flow of sewage	500,020 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	Yes, from wool washers, blanket makers, woollen manufacturers, dye works, carbonizers. About half the dry weather flow. *Note.* There are very few water closets in this Borough.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted	Oscar J. Kirby.
Name and qualification of chemist who has made the analyses.	None made.
(1) What was the nature of the chemical or chemicals used?	Lime and alumino-ferrric.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	10 grains of lime; $3\frac{1}{2}$ grains of alumino-ferric.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	The lime was varied from 10 to 60 grains per gallon, and the alumino-ferric from $3\frac{1}{2}$ to 16 grains per gallon.
(4) What is the capacity in gallons of the subsidence tanks?	240,000.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	400 tons of creamy sludge once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	From 1889 to 1893 intermittent. Since the latter date it has been continuous.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	It was not taken.
(*b*) What was the depth of these beds?	2 feet.
(*c*) What were the nature and size of the filtering material?	Coke, broken into 2-inch cubes.
(8) Give particulars of measurements made from time to time of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	None made. *Note.* This was not in any sense an ordinary experiment, *i.e.*, it was not done with the idea that we were experimenting, but that we were successfully treating the sewage first by precipitation and then by single contact in bacteria beds. We did not then know that the purification in the beds was bacterial, but we saw that the effluent was very much improved by being held up in the beds.
(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? I the measurement was made after resting, please give the duration of the resting.	

Appendix 9C.

(12) State method of working of contact beds, *i.e.* number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Once a day in 1889, three times a day in 1892, five times a day in 1893, when it was decided to run it continuously.
(13) State by what method the settled sewage was distributed on the beds.	Through $4\frac{1}{2}$ in. by $4\frac{1}{2}$ in. apertures in a brick wall.
(14) What was the average quantity of sewage in gallons dealt with daily?	In 1889, 300,000 gallons, increasing daily to the present time, when it is 1,000,000 gallons.
(15) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No, the pumps always raised the same quantity.
(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	None taken.
(17) Give (*a*) the average of the analyses of the final effluent from the beds. (*b*) the best analysis of the final effluent and date when sample was taken, and (*c*) the worst analysis of the final effluent and date when sample was taken. (*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed. (*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(18) Give a typical analysis of the crude sewage to which the experiment relates.	
(19) Between what dates was the treatment conducted? If there were any periods of rest, state their duration.	This was ordinary work, not done in the sense of making an experiment.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None made.
(21) Was any nuisance caused by the experimental works?	There was always a smell from the sludge lagoons.
(22) Is the treatment still proceeding? - - - - If so, may the Commission inspect the works, should they deem it desirable to do so?	No. But if the Commission did inspect they would see the contact beds which purified the sewage so well from 1889 till 1893.
(23) Give particulars of any other observations of importance which were recorded.	
(24) What inferences have been drawn from the treatment?	The following, viz.:— That in consequence of a great number of branch sewers being disconnected from natural streams and connected to the main intercepting sewers, the outfall works became too small to deal with the volume of sewage arriving there, with the result that the contact beds became continuous flow filters, which soon silt up and are as a consequence not nearly so economical for the treatment of Batley sewage as contact beds.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	It would be practicable, but it would be very costly.
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	Ten shillings.
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan	Two shillings.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note. 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

OSCAR J. KIRBY.

Signature of Officer under whose direction the treatment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT) AFTER CHEMICAL PRECIPITATION.

Name of authority	Calverley Urban District Council.
Population of district	3,000.
Water supply per head of the population	Ten gallons per day.
Estimated or measured dry weather flow of sewage	30,000 gallons per day.
Is any trade refuse taken into the sewers?	None whatever.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	William Walker, Surveyor to the Council.
Name and qualification of chemist who has made the analyses.	No analyses have been taken on behalf of the Council. The West Riding Rivers Board occasionally take samples of effluent.
(1) What was the nature of the chemical or chemicals used?	Alumino-ferric.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	About 35 lbs. per day is used.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	No.
(4) What is the capacity in gallons of the subsidence tanks?	22,500 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	Tanks emptied of sludge at irregular periods, depends on rainfall and amount of road detritus carried down.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	There are no coarse beds.
(b) What was the depth of these beds?	
(c) What were the nature and size of the filtering material?	
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	
(9) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	
(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Was not ascertained.
(b) What was the depth of these beds?	Three feet.
(c) What were the nature and size of the filtering material?	Engine ashes through a ¼-in. mesh.
(11) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	None taken.
(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Not ascertained.
(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.	Once per day and resting one day.

Appendix 9C.

(13) State by what method the settled sewage was distributed on the beds.	By corrugated sheet iron plates.
(14) What was the average quantity of sewage in gallons dealt with daily?	30,000.
(15) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Yes, to a certain extent, the storm overflow allowing more than the normal flow to go into and through the tanks and thus on to the beds. After a storm the surface of the beds are forked over to break up the skin of mud which is deposited on the surface.
(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	No analyses have been made on the Council's behalf.
(17) Give (*a*) the average of the analyses of the final effluent from the beds.	No observation.
(*b*) the best analysis of the final effluent and date when sample was taken, and	
(*c*) the worst analysis of the final effluent and date when sample was taken.	No observation.
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.	No observation.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	No observation.
(18) Give a typical analysis of the crude sewage to which the experiment relates.	No observation.
(19) Between what dates was the experiment conducted?	The works here are put down as a permanency and have been working some time now.
If there were any periods of rest, state their duration.	No observation, except that there are three beds and they are rested in rotation.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	No observation.
(21) Was any nuisance caused by the experimental works?	None whatever.
(22) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(23) Give particulars of any other observations of importance which were recorded.	
(24) What inferences have been drawn from the experiment?	That the system adopted is suitable for domestic sewage from such a place as Calverley.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state.	
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Fourpence.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

William Walker.
Signature of Officer under whose direction the experiment was conducted.

Appendix C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT) AFTER CHEMICAL PRECIPITATION.

Name of authority	Hendon Urban District Council.
Population of district	22,500. About 18,000 to 19,000 draining to the Outfall works at present.
Water supply per head of the population	About 35 gallons per day.
Measured dry weather flow of sewage	700,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Laundry work may be regarded as the staple industry of the place. This is also a residential suburb of London.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	In nearly all the roads there is a separate surface water drain as well as a sewer, and such surface water drain takes the water from the front roofs of most of the houses as well as all the water from the roads themselves.
Officer under whom the experiment has been conducted	Engineer and Surveyor.
Name and qualification of chemist who has made the analyses.	Mr. Frank Andrew, M.R.C.S., L.C.R.P., Medical Officer of Health, Hendon, N.W. Dr. Houston (crude sewage and resulting effluent from Col. Ducat's filter). Dr. Bevan, County Analyst.

(1) What was the nature of the chemical or chemicals used?	As to the proportion of the dry weather flow amounting to 450,000 gallons, *no* chemicals are now being used. As to 250,000 gallons forming the low-level flow 8 grains to a gallon of alumino-ferric or ferozone.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	Ditto.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Yes. Same proportion as No. 1 up to one million gallons, then no extra chemicals used.
(4) What is the capacity in gallons of the subsidence tanks?	3 large tanks combined capacity - 471,718 3 small „ „ „ - 205,662 Total in Gallons 677,380
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	About 350 tons wet sludge. Each tank cleaned once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous on six days. Quiescent one day for gauging (Wednesdays).
(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	120,000 gallons.
(*b*) What was the depth of these beds?	5 ft. average.
(*c*) What were the nature and size of the filtering material?	¾-in. clinker from breeze rejected by ⅛-in. sieve which removed the fine stuff.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Each of the three coarse bacteria beds hold 120,000 gallons of effluent. Tank effluent first put through two acres of land, laid out for intermittent downward filtration and then allowed to fill bacteria beds.
(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	The coarse beds hold same now as when first started in September 1898, so far as can be gauged.
(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material? (*b*) What was the depth of these beds? (*c*) What were the nature and size of the filtering material?	No "fine" beds at present.
(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not. (*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	No "fine" beds at present.

Appendix 9C.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Each of the three coarse bacteria beds filled and emptied once a day. Resting empty on Sundays.
(13) State by what method the settled sewage was distributed on the beds.	Carriers and galvanized sluice plates to convey the filtrate from the two acres of land laid out for intermittent downward filtration.
(14) What was the average quantity of sewage in gallons dealt with daily?	120,000 gallons each of the three filters.
(15) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	With 1 in. rain in 24 hours, if during rainy time the dry weather flow is increased four times, *i.e.*:—to 2,000,000 gallons. A better effluent obtained with small quantity of rain, compared with effluent during dry summer.
(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Samples allowed to settle made from time to time—not at stated or regular intervals.
(17) Give (*a*) the average of the analyses of the final effluent from the beds.	Free ammonia - - - - 1·4 parts per 100,000 Alb. „ - - - - ·14 „ „ „ The amount of albuminoid ammonia in the crude sewage has been found by Dr. Houston as high as 7·6 per 100,000 and by Dr. Bevan 8·4 parts per 100,000. The albuminoid ammonia is never less than three parts per 100,000 on an ordinary day and in dry weather is much more frequently run up to eight parts per 100,000 and over.
(*b*) The best analysis of the final effluent and date when sample was taken, and	Alb. NH_3 ·13 per 100,000 on February 13th 1899.
(*c*) The worst analysis of the final effluent and date when sample was taken.	Alb. NH_3 ·17 per 100,000 on May 18th 1900.
(*d*) The average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.	Cannot give this. Dr. Barwise found in the crude sewage 315 parts of solid matter per 100,000, 198·5 parts of which were in suspension. Nov. 20, 1897. Free ammonia - 6·16 parts per 100,000. Organic „ - 3·8 „ „ „ Professor Corfield found on May 10th, 1898:— Total solids - - - - 265·3 parts per 100,000. Fixed - - - - 115·1 „ „ „ Volatile - - - - 150·2 „ „ „
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Dr. Bevan. Total solids dried at 212° Fahr. - 13·4 Solids in suspension - - - none Solids in solution - - - - 130·4 Mineral matters in solution - - 1·43 Alb. ammonia - - - - ·143 Oxygen consumed in three hours - ·51 Chlorine - - - - - 14·3 Dr. Bevan states that the percentage of purification is 93 per cent. on the albuminoid ammonia, and 82 per cent. on the oxygen.
(18) Give a typical analysis of the crude sewage to which the experiment relates.	*See* 14 (*d*) *ante*.
(19) Between what dates was the experiment conducted?	September 1898 and still going on.
If there were any periods of rest, state their duration.	Sundays, bacteria beds, always resting. Week days, each bed filled once a day.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	It has been noted that during the time sewage effluent was in contact with the filtering media in bacteria beds, temperature increased on an average 1° Fahr. only (thermometer placed two feet below the surface of bed).
(21) Was any nuisance caused by the experimental works?	There is none. (Far less than on the land.)

Appendix 9C.

(22) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	With pleasure any time.
(23) Give particulars of any other observations of importance which were recorded.	
(24) What inferences have been drawn from the experiment?	That it has been demonstrated beyond a doubt that open septic or detritus tanks, with a capacity of not less than one day's dry-weather flow, with subsequent filtration through land laid out on the intermittent downward filtration principle, and afterwards contact with bacteria, will produce an effluent which is not injurious to fish life, as the volume of the effluent is about ten times the volume of the flow in the River Brent, into which it discharges, as for many weeks in the year the volume of water flowing in the River Brent is under 22,000 gallons, gauged by S.S. Grimley. It will be noted that the sewage is particularly foul, being little more than a solution of soap on three days a week, in addition to the dense domestic sewage in all days. A better effluent can be obtained from artificial bacteria beds than from the clay land forming the site of the outfall works.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Quite practicable.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	10*s.* per head first cost of bacteria beds in addition to the present open septic or detritus tanks.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	2*l.* 10*s.* to 3*l.* per million gallons of dry weather flow. If all the water taken into account the mean would be 25*s.* to 30*s.* per million gallons treated. But it is far better to take the cost on the dry weather flow. Let this be understood to be uniform throughout the replies, *i.e.*, cost to be given on the dry-weather flow, which is the only reliable data.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

S. Slater Grimley,
Assoc.M.Inst.C.E.

Signature of Officer under whose direction the experiment was conducted.

Form C.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT) AFTER CHEMICAL PRECIPITATION.

Name of authority - - - - - - - -	Heywood Corporation.
Population of district - - - - - - -	26,000.
Water supply per head of the population - - - -	20 gallons per day.
Estimated or measured dry weather flow of sewage -	800,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Partly from breweries and dye works. About 5 per cent
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted.	Sewage works manager.
Name and qualification of chemist who has made the analyses.	Joshua Bolton (advanced) S.K.
(1) What was the nature of the chemical or chemicals used?	Alumino-ferric.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	$8\frac{1}{2}$ grains.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Varied according to strength.
(4) What is the capacity in gallons of the subsidence tanks?	675,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	380 tons per week (wet sludge).
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	No coarse beds.
(b) What was the depth of these beds?	Ditto.
(c) What were the nature and size of the filtering material?	Ditto.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No second contact beds.
(9) What was the water-holding capacity of the coarse beds at end of experiment?	Ditto.
If the measurement was made after resting, please give the duration of the resting.	
(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	About one-third.
(b) What was the depth of these beds?	4 feet 3 inches.
(c) What were the nature and size of the filtering material?	Sand and graduated coke.

Appendix 9C.

(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	No actual measurement taken until 3 months after commencement. Then 34 per cent. directly after emptying.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	34 per cent. No resting.
(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	3 fillings per day; 2 hours filling, 2 hours standing full, ½ hour emptying, 3½ hours resting.
(13) State by what method the settled sewage was distributed on the beds.	By open troughs.
(14) What was the average quantity of sewage in gallons dealt with daily?	200,000 (on the beds).
(15) Was the quantity of sewage dealt with increased in time of storm?	Slightly.
If so, state to what extent, and how the results were affected by such increase.	Good results.
(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Daily. Bottle shaken.
(17) Give (*a*) the average of the analyses of the final effluent from the beds;	(*a*) Oxygen absorbed 4 hours - - - - 1·2 Chlorine - - - - - - - - - 6·0 Free Ammonia - - - - - - - - 1·3 Abuminoid Ammonia - - - - - - - ·14 N as Nitrates - - - - - - - - 0·44 N as Nitrites not estimated.
(*b*) the best analysis of the final effluent and date when sample was taken and	(*b*) Oxygen absorbed 4 hours - - - - 0·4 Chlorine - - - - - - - - - 3·2 Free NH_3 - - - - - - - - ·16 Albuminoid Ammonia - - - - - - 0·18 Nitrates, traces, Oct. 31st 1900.
(*c*) the worst analysis of the final effluent and date when sample was taken;	Oxygen absorbed in 4 hours - - - - Chlorine - - - - - - - - - 9·1 Free Ammonia - - - - - - - - 1·1 Albuminoid Ammonia - - - - - - ·21 N as Nitrates, nil.
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	Not estimated.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Traces. Non-putrescible.
(18) Give a typical analysis of the crude sewage to which the experiment relates.	Average of many samples. Oxygen absorbed in 4 hours - - - - 7·7 Chlorine - - - - - - - - - 5·9 Free Ammonia - - - - - - - - 2·10 Albuminoid Ammonia - - - - - - ·51 Nitrates, nil.
(19) Between what dates was the experiment conducted?	Experiments continuous.
If there were any periods of rest, state their duration.	One day per week.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	Mean about 52° Fahr.
(21) Was any nuisance caused by the experimental works?	No.
(22) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(23) Give particulars of any other observations of importance which were recorded.	

The surface of the beds slowly became covered with a slimy deposit which obstructed the flow. This deposit was removed every 4 weeks. The beds have been at work over 3 years and are still working well.

(24) What inferences have been drawn from the experiment?	The works are most successful of their kind, embracing chemical precipitation and bacterial filtration.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(a) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	About 1*l*. 5*s*. per head.
(b) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	About 1*s*. 6*d*. per head, excluding interest on loans, &c.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

JOSHUA BOLTON.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT) AFTER CHEMICAL PRECIPITATION.

Name of authority	Huddersfield Corporation.
Population of district	105,000.
Water supply per head of the population	Domestic purposes 14 gallons per day. Trade purposes 9 gallons per day.
Estimated or measured dry weather flow of sewage	Measured 7,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes, a large quantity, chiefly from the scouring, dyeing, and finishing of wool, &c.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	29 per cent. of dry weather flow.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	A large quantity of storm and surface water enters the sewers.
Officer under whom the experiment has been conducted	Borough engineer.
Name and qualification of chemist who has made the analyses.	Percy Coward.
(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	3·4 lime (CaO). 2·6 copperas.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Sufficient chemicals were added to cause almost the whole of the matter in suspension to coagulate and settle in about 10 minutes. Generally during the early hours of the morning no chemicals would be needed. About noon as much as 12 grains of lime and 10 grains of copperas per gallon were required.
(4) What is the capacity in gallons of the subsidence tanks?	23 tanks, each 55,000 gallons capacity. Total capacity 1,265,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	892 cubic feet of liquid sludge per million gallons (about 90 per cent. water); or 3·9 tons of press cake per million gallons (about 54 per cent. water). 3 weeks.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	First contact beds (not coarse). No. 7, 19,230 gallons. No. 10, 19,940 gallons. No. 11, 17,660 gallons. No. 12, 19,200 gallons. *Note* 1.—No. 11 bed was constructed during wet weather. *Note* 2.—There are 24 beds for the single contact of the tank effluent. The above four are representative ones.
(b) What was the depth of these beds?	(b) 3 ft. 3 in.
(c) What were the nature and size of the filtering material?	(c) No. 7, destructor clinker, 6 in. rough, 2 ft. 9 in. of $\frac{3}{16}$ in. to 1 in. material. No. 10, ordinary clinker, 5 in. rough, 2 ft. of $\frac{1}{4}$ in. to $1\frac{1}{2}$ in., and 10 in. of $\frac{1}{4}$ in. to $\frac{3}{8}$ in. No. 11, ordinary clinker, 6 in. rough, 1 ft. 9 in. of $\frac{1}{2}$ in. to $1\frac{1}{2}$ in., and 1 ft. of $\frac{3}{16}$ in. to $\frac{1}{2}$ in.. No. 12, ordinary clinker, 6 in. rough, 2 ft. 9 in. of $\frac{3}{16}$ in. to 1 in.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	See table below.

No. 10 Bed.

Date.	Capacity (gallons).	Previous rest.
1898. 25th July	19,940	initial capacity.
29th July	17,030	3 hours.
6th September	15,580	3 "

* The fifth time of filling after resting three weeks.

Appendix 9C.

Question	Answer
(9) What was the water-holding capacity of the coarse beds at end of experiment?	See table below.
If the measurement was made after resting, please give the duration of the resting.	Each after two hours rest. *Note.*—These beds are still in operation.
(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	We have no large fine or secondary beds for the second contact of the tank effluent, but a small one has been constructed in the laboratory for giving the effluent from No. 10 bed a second contact.
(*b*) What was the depth of these beds?	This small secondary bed is 2 ft. 8 in. deep.
(*c*) What were the nature and size of the filtering material?	Furnace clinker ¼ in. to ¾ in., taken from No. 10 bed.
(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	None.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	3 fills per day. (*a*) 1½ hours. (*b*) 7½ „ (*c*) 1½ „ (*e*) 13½ „
(13) State by what method the settled sewage was distributed on the beds.	Trough.
(14) What was the average quantity of sewage in gallons dealt with daily?	5,500,000 gallons in tanks, of which 700,000 gallons receive one contact.
(15) Was the quantity of sewage dealt with increased in time of storm?	
If so, state to what extent, and how the results were affected by such increase.	No.
(16) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	The samples have been analysed daily. Neither filtered through paper, nor allowed to clear by standing.

Table to (9):

No.	——	——
7	13th August 1900 - - - - -	13,090
10	14th January 1901 - - - - -	9,040
11	„ „ - - - - -	8,720
12	„ „ - - - - -	8,620

(17) Give (*a*) the average of the analyses of the final effluent from the beds;

——	Date.	Albuminoid Nitrogen.	Oxygen absorbed in 4 hours at 80° F.
(*a*) Single contact - (No. 10 Bed effluent.)	July 1898 to March 1899.	·103	2·16
	March 1899 to March 1900.	·115	2·33
	June 1900 to January 1901.	·095	1·93
Double contact -	June 1900 to January 1901.	·059	1·11

(*b*) the best analysis of the final effluent and date when sample was taken; and

——	Date.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Oxygen absorbed. 3 min.	Oxygen absorbed. 4 hours.
(*b*) Single contact	16 Jan. 1899	·20	·023	·19	·59
Double contact	8 Aug. 1900	·01	·029	·20	·46

(*c*) the worst analysis of the final effluent and date when sample was taken;

——	Date.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Oxygen absorbed. 3 min.	Oxygen absorbed. 4 hours.
(*c*) Single contact	12 Sept. 1899	·73	·194	1·49	4·19
Double contact	12 Sept. 1900	·26	·108	·60	1·64

Question	Answer
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	Average of occasional analysis— Mineral, 1·54. Volatile, 4·69. Total, 6·23.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Only traces of suspended matter are present in the effluent. In no case has the effluent from double contact become putrescent when kept for seven days at 80° F. in a stoppered bottle (completely filled).

Appendix 9C.

(18) Give a typical analysis of the crude sewage to which the experiment relates.	Albuminoid nitrogen - - ·608 Total organic nitrogen - 1·23 Ammoniacal nitrogen - 1·24 Nitrous and nitric nitrogen ·02 Oxygen absorbed in 4 hours at 80° F.:— Sample shaken - - 9·71 Sample settled - - 7·69 Sample filtered - - 5·31 Chlorine - - - - 14·1 Reaction—Slightly alkaline to litmus. Solids. In suspension— Mineral - - 16·4 Volatile - - 18·2 Total - - 34·6 In solution— Mineral - - 59·7 Volatile - - 11·8 Total - - 71·5 Total solids— Mineral - - 76·1 Volatile - - 30·0 Total - - 106·1
(19) Between what dates was the experiment conducted?	Commenced July 1898, and still in progress.
If there were any periods of rest, state their duration	All the beds are rested on Sundays. The first contact bed, No. 10, had a rest of 10 days in August 1899, 21 days in February 1900. 12 days in November 1900.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None made.
(21) Was any nuisance caused by the experimental works?	No.
(22) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(23) Give particulars of any other observations of importance which were recorded.	From experiments made, the following conclusions have been drawn:— 1st. That beds constructed of clinker obtained from the destructor on the works are as effective as those constructed of clinker or furnace ashes from the gas and various works in the neighbourhood. The destructor clinker is of a very different nature to the other clinker. 2nd. That beds constructed with the large and small pieces mixed, are slightly more effective than those in which the various sized pieces are separated or graduated. 3rd. That by lengthening the period of contact a slightly greater degree of purification only is effected. 4th. That the efficiency of the beds increases with the length of time they have been in operation.
(24) What inferences have been drawn from the experiment?	That it would be possible to satisfactorily purify the sewage of Huddersfield by chemical precipitation, settlement and contact beds. That there are periods of the day, and frequently during the whole day, when single contact would suffice for the purification of the tank effluent, and that at other times double contact would be necessary. The accumulation of irreducible matter in the beds is a serious item, but by freeing the tank effluent from as much suspended matter as possible, and by using only a very moderate quantity of lime this will be minimised. There is no doubt that portions of the beds will require taking out and washing or riddling from time to time.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	£1 2*s*. 10*d*.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan?	10·3*d*.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:-

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

J. L. Campbell, M.Inst. C.E.,
Signature of Officer under whose direction the experiment was conducted.

Form C. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Northern Outfall.—One-acre coke bed fed with screened and sedimented sewage.

Name of authority - - - - - - -	London County Council.
Population of district - - - - - - - (Sewage derived from London north of Thames.)	3,251,974 (1896).
Water supply per head of the population - - -	34·8 gallons per day (1900).
Estimated or measured dry weather flow of sewage -	123,000,000 gallons per day (1900).
Is any trade refuse taken into the sewers?	
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	All the trade refuse from the districts drained is taken into the sewers. The quantity is not known.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	Professor Clowes, D.Sc.
Name and qualification of chemist who has made the analyses.	Mr. E. B. Pike.
(1) What was the nature of the chemical or chemicals used?	Lime and ferrous sulphate.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	5 grains of lime and 1 grain of ferrous sulphate per gallon of sewage. An invariable quantity of 780 cwt. of lime is used during the 24 hours. The proportion is, however, varied from hour to hour with average variation in the nature and volume of the sewage. The hourly quantity varies from 20 cwt. between 6 and 8 p.m. to 44 cwt. between 2 and 6 p.m.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	About 20 million gallons, but only about 700,000 gallons per day are passed through the one-acre bacteria bed.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	From thirty to thirty-five thousand tons of sludge are produced per week. The tanks are cleaned about every 100 hours.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the bed when filled with the filtering material?	717,503 gallons or 41·9 per cent.—only one contact bed was used in these experiments. Its area was 5,067 square yards.
(b) What was the depth of these beds?	6 feet.
(c) What were the nature and size of the filtering material?	The lower 3 feet consisted of unsifted "pan breeze," the upper 3 feet of sifted coke fragments about the size of walnuts.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Capacity in middle of May, 1898, 40·8 per cent. Early in July, 1898, 37·7 per cent. During this period the bed was filled once a day, and the capacity was taken after the bed had been draining from 20 to 22 hours. Capacity— 29 July, 1898 - 29·7 per cent - From July 4 the bed was filled twice a day. 8 Nov. - - 39·7 ,, ,, - The bed had been resting empty from July 29 to admit of structural alterations. 11 Mar., 1899 - 29·1 ,, ,, - Continues work from Nov. 8. 8 May, ,, - 38·4 ,, ,, - The bed had been resting empty from Nov. 11. 30 Dec. ,, - 2·66 ,, ,, - Continues working from May 8. The above five capacities were taken after the bed had been draining from 8 to 10 hours. The data of the capacity of this bed are not satisfactory or conclusive owing to the nature of the coke constituting the lower three feet of the bed.

Appendix 9C.

(9) What was the water-holding capacity of the coarse beds at end of experiment?

If the measurement was made after resting, please give the duration of the resting

(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

No fine beds were used.

(*b*) What was the depth of these beds?

(*c*) What were the nature and size of the filtering material?

(11) (*a*) Giving particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

One or two fillings per day.
(*a*) About 1 hour.
(*b*) 2 hours.
(*c* & *e*) 9 to 10 or 22 to 24 hours.

(13) State by what method the settled sewage was distributed on the beds.

Through wooden troughs with branches at intervals.

(14) What was the average quantity of sewage in gallons dealt with daily?

From 350,000 to 1,100,000 gallons.

(15) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily averages were analysed and the samples were filtered through paper previous to analysis except in the case of the estimations of total putrescible matter

(17) Give (*a*) the average of the analyses of the final effluent from the beds.

Averages for 1900:—

Oxygen absorbed from permanganate in four hours at 80° F.:	
By the total putrescible matter. - -	0·998
By the dissolved putrescible matter. -	0·835
Nitrous nitrogen - - - - - -	0·0539
Nitric nitrogen - - - - - -	1·0391

(*b*) the best analysis of the final effluent and date when sample was taken, and

28th October, 1901.

(*c*) the worst analysis of the final effluent and date when sample was taken.

29th May, 1901.

—	(*b*)	(*c*)
Oxygen absorbed from permanganate in four hours at 80° F.:		
By the total putrescible matter.	0·396	1·690
By the dissolved putrescible matter.	0·286	1·636
Nitrous nitrogen - - -	0·0300	0·0800
Nitric nitrogen - - -	1·1297	1·6368

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

13 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Not estimated. None putrescible.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

Average for 1900:—

Oxygen absorbed from permanganate in four hours at 80° F.:	
By the total putrescible matter. - -	11·546
By the dissolved putrescible matter. -	5·543
Solids in suspension - - - - - -	52·0
Solids in solution - - - - - -	98·0

Appendix 9C.

(19) Between what dates was the experiment conducted?	12th May, 1898, to date.
If there were any periods of rest, state their duration.	Every Sunday. 18 days extra during 1900. 6 days extra during 1901.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None made.
(21) Was any nuisance caused by the experimental works?	No.
(22) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(23) Give particulars of any other observations of importance which were recorded.	During the last few years, since the extra 3 feet of coke were placed upon the original lower 3 feet, the lower layer has become compacted together and does not become drained from liquid when the bed is emptied. Hence the available capacity of the bed for working purposes is practically the upper 3 feet only. This seems to have been due to the use of unsifted coke for the lower part. It does not appear to affect in any way the quality of the effluent.
(24) What inferences have been drawn from the experiment?	That the coke bed when fed intermittently with sewage which has been roughly screened, then mixed with chemicals and subjected to sedimentation, effects a satisfactory purification, and that the effect is produced through an unlimited period of time without any loss of capacity of the bed, but that the coke used should be sifted and be of hard and suitable quality.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analysis may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen;

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

FRANK CLOWES,
Chief Chemist to the London County Council.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

(Coke and Cinder Beds (Roscoe's.)

Name of authority	Manchester.
Population of district	400,000 in 1896 to 550,000 in 1900.
Water supply per head of the population	28 gallons per day, Domestic use, 17; trade purposes, 11. (1900.)
Estimated or measured dry weather flow of sewage	15,000,000 (estimated) in 1896 to 27,000,000 in 1900 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Breweries, dye and bleach works, galvanising works, grease refineries, tanneries, manufactories of tar products, rubber goods works, tripe-dressing works, and mineral water manufactories. 4 to 5 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm-overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1. In certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Sir Henry Roscoe, F.R.S. F. Scudder F.I.C. Gilbert J. Fowler, M.Sc. (Vict.I.). F.I.C. (Supt.)
Name and qualification of chemist who has made the analyses.	W. Clifford, A.R.C.Sc.I. Edward Ardern, B.Sc. (Vict.). H. D. Bell, A. C. Oddie, E. Hadfield, } Junior Assistants. Under the direction of G. J. Fowler (Supt.)

(1) What was the nature of the chemical or chemicals used?

Date.	Cal.	Copperas.	Ferric Sulphate.	Alumina Ferric.
1896	6·28	6·04		Small amount occasionally used
1897	5·32	5·29		
1898	4·85	5·34	Used for short time	
1899	2·68	2·24		

The above numbers are calculated on the average flow including storm water.

(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?

Addition of chemicals suspended altogether in case of heavy storm, and latterly, often in the early hours of the morning when the sewage is dilute.

The addition of chemicals is regulated at other times by (1) the character of the precipitate produced in a test glass, and (2) reaction with phenol phthalein.

(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations

The amount of lime has to be increased considerably during the presence of acid waste or iron pickle, as much as 24 *grains Cal. per gallon* being added. The amount of both lime and copperas have to be increased in presence of dye-waste, as much as 29 *grains Cal. and* 12 *grains copperas* per gallon being added.

(4) What is the capacity in gallons of the subsidence tanks.

11 tanks.
Total capacity, 12,375,000 gallons.

(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.

From 3,000 to 4,000 tons (90 per cent.).
About once a week.

(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.

Continuous.

(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

(*b*) What was the depth of these beds?

3 feet.

(*c*) What was the nature and size of the filtering material?

(1) coke. (2) clinker. Graded as follows, from the bottom upwards:—

12 inches rough.
9 „ sized to $1\frac{1}{2}$ in. mesh.
6 „ sized to $\frac{3}{4}$ in. mesh.
6 „ to pass $\frac{3}{8}$ in. and rejected by $\frac{1}{8}$ in.
3 „ washed gravel.

Appendix 9C.

(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

(9) What was the water-holding capacity of the coarse beds at end of experiment?

If the measurement was made after resting, please give the duration of the resting.

(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(b) What was the depth of these beds?

(c) What was the nature and size of the filtering material?

(11) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

Date.	Coke (Capacity in Gallons.)	Cinder (Capacity in Gallons.)	Remarks.
1895. Dec. 19th -	1,750	1,750	
1897. April 26th -	1,296	1,260	1 hours rest.
April 28th -	1,332	1,404	8 ,,
May 27th -	1,380	1,477	17 ,,

1898. Jan. 5th -	1,260	1,350	After 2 hrs. rest.
Jan. 7th -	1,278	1,368	After 15 hrs. rest.
Jan. 24th -	1,368	—	Fortnight's rest, then once filled. and $1\frac{1}{2}$ hrs. rest.
June 17th -	1,188	1,332	$1\frac{1}{2}$ hours rest.
Nov. 25th -	1,224	1,368	After $1\frac{1}{2}$ hrs. rest.
1899. Jan. 7th -	1,188	1,296	After 1 hrs. rest.
Jan. 9th -	1,278	1,368	After 20 hrs. rest.
April 26th -	1,152	1,260	After $1\frac{1}{3}$ hrs. rest.
Oct. 6th -	1,296	1,224	After 3 hrs. rest.
1900. Jan. 2nd -	1,224	1,188	After 9 days rest.
Jan. 2nd -	1,152	1,116	After $2\frac{1}{2}$ hrs. rest.
April 24th -	1,188	1,224	After 20 dys rest.
April 26th -	1,044	1,044	After $2\frac{1}{3}$ hrs. rest.
June 28th -	972	1,008	After $2\frac{1}{2}$ hrs. rest.
Sept. 4th -	1,116	1,116	After 6 days rest.
Sept. 6th -	1,008	1,008	After $3\frac{1}{2}$ hrs. rest.
1901. Jan. 7th -	1,008	1,089	After 36 hrs. rest.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

Method of working Coke and Cinder Beds:

Date.	No. of fillings per day.	Time of filling.
Dec. 19th, 1895 to Jan. 5th, 1896	1	
Jan. 6th to Jan. 21st, 1896 - -	2	
Jan. 22nd, 1896 to Jan. 1897	3	At 8 a.m., 12 noon, and 4 p.m.
Jan. to Mar. 8th, 1897 - -	3	,, 8 a.m., 12 noon, and 12 mdt.
Mar. 8th to April 21st, 1897 -	3	,, 8 a.m., 12 noon, and 4 p.m.
April 21st to May 5th, 1897 -	3	,, 8 a.m., 4 p.m., and 12 mdt.
May 12th to Dec. 15th, 1899 -	3	,, 8 a.m., 12 noon, and 4 p.m.
Dec. 16th, 1898 to May 31st, 1900	4	,, 8 a.m., 12 noon, 4 p.m., and 12 midnight.
*May 31st to present time - -	3	,, 8 a.m., 12 noon, and 4 p.m.

* During this period the beds have been worked on three fillings per day, with one week's rest for each working period of three weeks.

In general the cycle of operations in each case being:—

(*a*) $\frac{1}{2}$ hour.
(*b*) 2 hours.
(*c*) $\frac{1}{2}$ hour.
(*e*) Remainder of 24 hours according to the number of fillings.

The beds have always rested on Sundays.

(13) State by what method the settled sewage was distributed on the beds.

By means of iron channels, which pass up each side of the beds.

(14) What was the average quantity of sewage in gallons dealt with daily?

Coke 3,210 gallons per day, cinder 3,230 gallons per day.

(15) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase.

No.

16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before analysed.

Daily except Sundays. Samples were shaken before analysis.

Appendix 9C.

(17) Give (*a*) the average of the analyses of the final effluent from the beds.

The following numbers are the average of daily analyses of the filtrates from the coke and cinder beds for the various periods given:—

Date.	Four Hours Oxygen Absorption.		Incubator Test. 3 minutes Oxygen Absorption. Before Incubation.		Incubator Test. 3 minutes Oxygen Absorption. After Incubation.		Putrescibility.		Ammoniacal Nitrogen.		Albumnioid Nitrogen.	
	Coke.	Cinder.	Coke.	Cinder.	Coke.	Cinder.	Coke.	Cinder.	Coke.	Cinder.	Coke.	Cinder.
Dec. 19, 1895, to Jan. 5, 1896 (1 filling per day.)	·94	1·19	—	—	—	—	—	—	2·16	1·94	·142	·136
Jan. 6—Jan. 21st, 1896 (2 fillings per day.)	1·30	1·28	—	—	—	—	—	—	2·01	2·09	·117	·105
Jan., 1896, to Dec., 1898 (3 fillings per day.)	1·73	1·39	·97	·74	·88	·61	31½/296	† 4½/310	1·93	1·63	·148	·128
Jan., 1899, to May 31, 1900 (4 fillings per day.)	3·41	2·61	2·04	1·51	2·44	1·53	65/106	28/112	1·70	1·50	·140	·120
May 31—Dec. 26, 1900* (3 fillings per day. Alternate periods of 3 weeks' work and 1 week's rest.)	2·91	2·27	1·63	1·16	1·83	1·04	54/120	19½/126	1·71	1·34	·140	·140

† The figures for 3 minutes' Oxygen Absorption refer to the average of daily analyses from April 21st, 1896, to December, 1898. The putrescibility numbers, to samples analysed from January to December, 1898, only.

The figures for 4 hours' oxygen absorption, ammoniacal and albuminoid nitrogen, refer to the average of daily analyses from May 31st to July 11th, 1900.

(*b*) The best analysis of the final effluent and date when sample was taken, and

(*c*) The worst analysis of the final effluent and date when sample was taken.

(*d*) The average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

About 5·5 parts per 100,000.

(*e*) The average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Practically nil.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily samples of sewage for the periods given. The numbers for periods Sept. to Dec. 1897, and June to Dec. 1900 refer to crude sewage, the numbers for the other periods to settled sewage.

Period.	Four Hours. Oxygen Absorbed.	Three Minutes Oxygen Absorbed.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
Year 1896 (Settled Sewage)	3·86		2·50	0·447	
Jan.—Sept. 1897 (Settled Sewage)	6·18	2·78	2·43	0·39	15·0
Sept.—Dec. 1897 (Crude Sewage)	10·86	4·94	2·49	0·66	15·4
Year 1898 (Settled Sewage)	7·36	3·75	2·27	0·37	16·2
Year 1899 (Settled Sewage)	6·75	3·62	2·30	0·33	16·0

June 27—Dec. 1900 (Crude Sewage)	11·11	5·49	2·23	0·59	17·0

(19) Between what dates was the experiment conducted?

If there were any periods of rest, state their duration.

From December 1895 until the present time, exclusive of Sundays, the total amount of rest in five year amounted to the following:

Coke, 33 weeks. Cinder, 29 weeks.

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

(21) Was any nuisance caused by the experimental works?

No.

(22) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Yes.

Appendix 9C.

23) Give particulars of any other observations of importance which were recorded.

Maintenance of Beds.—During the first few years the surface of these beds required attention only very occasionally, and on the average not more than eight operations per annum were needed, in many of these cases a slight raking being all that was required. Frequently, however, the beds have been loosened with a fork to a depth of one foot.

Throughout the five years no material has been renewed; it has been found, however, that in process of time the surface of the beds has risen considerably above its original level, and this accumulated material has been on two occasions taken off and piled up in heaps on the bed. After the first of these occasions, when the piled material was sufficiently recovered, it was put back in the place of clogged portions of the surface which had been in their turn removed and piled. Recently, by way of experiment, the top foot or so of the material of the beds has been taken out, washed, re-screened and put back; a considerable increase in capacity resulted, though the level of the surface was several inches lower than previously. The washed-out portions rapidly dry to a perfectly inoffensive earthy residue; in the case of the cinder bed a considerable amount of broken-down clinker was present in the washed-out material. Two kinds of washed-out material were distinguished, a heavy and light, the former being easily spadeable, the latter forming a thin slurry which could be readily drained to a jelly-like mud when run on to the surface of an adjacent bed. The cost of this operation, on the small scale, averaged about 1s. 6d. per square yard. During the last year's working the surface of the beds, especially in wet weather, tended to become waterlogged; in such cases, instead of filling the bed with tank-effluent and allowing the ordinary time of contact, the liquid was allowed to percolate slowly through, the exit valve being kept open. The quantity thus dealt with was equal to one filling, and the purification was not seriously inferior.

(24) What inferences have been drawn from the experiment?

Maintenance of Beds.—Experience has shown that it is not advisable to loosen the bed below the top few inches, lest the fine suspended matter, accumulated on the surface, penetrates into the body of the bed.

In order to keep the beds open it appears well to take only the top few inches, and from time to time to turn the surface over to this depth.

From time to time it will probably be necessary to remove the top surface to a depth of a few inches and pile the material in heaps on the bed to recover, its place being taken by material already similarly treated.

It does not appear economical to wash this upper layer, but it should not be difficult to devise a method by which the looser material beneath should be washed at a reasonable cost, from time to time.

Purity of Effluent.—In judging of the results given, it should be borne in mind that in many cases where a sample has been returned as putrefactive, it is very much less so than the original tank-effluent, and in all probability a brief exposure to air would be all that is necessary to render it non-putrefactive.

(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

Cost of 50 acres of filters	£150,737
Cost of 26 acres storm beds	40,505
Sundries	8,758
	£200,000

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;

Say 8s. per head.

Amount already spent - 8s. per head of population.

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

(*b*) 1s. per head, made up as follows:—

Raking, &c. of surface of 50 acres	£500
Washing of top foot every 5 years at 1s. 6d. per sq. yd.	3,500
Attendance on sluices, &c.	1,000
Present cost of treatment	20,000
Annual cost	£25,000

Note 1. It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

GILBERT J. FOWLER,
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Peat filter.

Name of authority	Manchester.
Population of district	430,764.
Water supply per head of the population	gallons per day.
Estimated or measured dry weather flow of sewage	17,230,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm-overflows are provided at various points, which are supposed to come into action at a dilution of 5 to 1; in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted.	Gilbert J. Fowler, M.Sc. (Vict.) F.I.C.
Name and qualification of chemist who has made the analyses.	H. D. Bell, junior assistant under G. J. Fowler.
(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	CaO. 5·32. $FeSo_4 7H_2O$ 5·29
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	11 tanks. Total capacity 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the bed when filled with the filtering material?	Could not be determined.
(b) what was the depth of the bed?	3 feet 6 inches.
(c) what was the nature and size of the filtering material?	Peat, cut in blocks about a foot square, from Carrington.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	
(9) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	
(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(b) What was the depth of these beds?	
(c) What was the nature and size of the filtering material?	
(11) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.	

Appendix 9C.

(13) State by what method the settled sewage was distributed on the beds.	By means of wooden shoots.
(14) What was the average quantity of sewage in gallons dealt with daily?	
(15) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	
(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	
(17) Give (*a*) the average of the analyses of the final effluent from the beds;	Four hours' oxygen absorption. 0·70 parts per 100,000.
(*b*) the best analysis of the final effluent and date when sample was taken; and	
(*c*) the worst analysis of the final effluent and date when sample was taken;	
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	About five to six parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Nil.
(18) Give a typical analysis of the crude sewage to which the experiment relates.	
(19) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	A few days during March, 1897.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(21) Was any nuisance caused by the experimental works?	No.
(22) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(23) Give particulars of any other observations of importance which were recorded.	On admitting the tank effluent, the surface of the peat was covered in a very few minutes, shewing that but little water could penetrate into the interior of the filter. In process of time the water gradually disappeared, the peat swelling like a sponge, causing the wooden carriers to bend. Although the valve at the exit was left open, no more than a slight trickle could at any time be obtained from it, showing that the water was held up in the pores of the filter. On testing with an iron rod, the peat was found to be quite soft throughout. After repeated trials the rate of filtration was not found to increase, and the experiment was then abandoned.
(24) What inferences have been drawn from the experiment?	That peat is a most unsuitable material for purifying effluent.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state (*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers? (*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan?	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or o "Septic" action is produced.

Gilbert J. Fowler,
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Coal Filter.

Name of authority - - - - - - - -	Manchester.
Population of district - - - - - - -	430,000 at commencement; increased to 550,000.
Water supply per head of the population- - - -	gallons per day.
Estimated or measured dry weather flow of sewage- -	17,230,000 gallons to 27,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1, in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted.	Gilbert J. Fowler, M.Sc., F.I.C. (Superintendent). W. Clifford, A.R.C. Sc.I. Edward Ardern, B.Sc. (Vict.). H. D. Bell, A. C. Oddie, E. Hadfield } Junior Assistants.
Name and qualification of chemist who has made the analyses.	Under the direction of G. J. Fowler (Supt.).
(1) What was the nature of the chemical or chemicals used?	Chiefly lime and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	1897 CaO. 6·28 $FeSO_47H_2O$ 6·04 1898 do. 4·85 do. 5·34 1899 do. 2·68 do. 2·24 Above numbers calculated on the average daily flow.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 to 4,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the bed when filled with the filtering material?	Not determined.
(b) What was the depth of these beds?	3 feet.
(c) What was the nature and size of the filtering material?	Coal. 6 inches of large lumps at the bottom, 2 feet 6 inches all sizes up to ½-inch. On August 11th, the material was taken out and the dust removed by washing.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of bed, stating in each case whether the measurement was made after resting or not.	(see table below)
(9) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	

Date.	Capacity in Gallons.	Remarks.
28th April 1897 -	828	
6th Oct. 1897 -	1,260	The dust was washed out of material on August 11th.
26th Jan. 1898 -	1,026	After 2½ hours rest.
20th June „	828	„ 13½ „
16th Oct. 1899 -	756	„ 23½ „

(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds?

(*c*) What was the nature and size of the filtering material?

(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

For the most part (except from July 28th to Nov. 24th, 1897, when it was worked as a continuous filter), up to the beginning of 1899, the bed was filled *3 times per day*, at 8 a.m., 12 noon,and 4 p.m.

From 1899 to the end of the experiment, the bed received, in general, *4 fillings per day*. During this latter period, 2 short flushes were frequently given instead of one ordinary filling.

(13) State by what method the settled sewage was distributed on the beds.

By means of wooden shoots. From February 24th-July 31st, 1897 = 1,900 gallons per day.

(14) What was the average quantity of sewage in gallons dealt with daily?

From November 14th, 1897, to January 27th, 1900 = 2,340 gallons per day.

(15) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(17) Give (*a*) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses for the two working periods:—

i. February 24th to July 31st, 1897.
ii. November 14th, 1897 to January 27th, 1900.

Date.	Four hours' Oxygen Absorption	Incubator test, 3 mins. Oxygen Absorption.		Putres-cibility.	Ammo-niacal Nitrogen.	Albu-minoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
		Before	After.						
February 24th to July 31st, 1897	1·19	·43	·36	11½/105	1·68	·124			
November 14, 1897, to January, 1900	1·90	1·00	1·03	110/576	1·35	·119			

(*b*) the best analysis of the final effluent and date when sample was taken; and

(*c*) the worst analysis of the final effluent and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

About 5 to 6 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Slight amount.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily samples of *Settled Sewage* for the years 1897, 1898, and 1899:—

Year.	Four hours' Oxygen Absorption.	3 mins. Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
*1897	6·18	2·78	2·43	·39	15·0
1898	7·36	3·75	2·27	·37	16·2
1899	6·75	3·62	2·30	·33	16·0

* The figures for 1897 refer to the average from January to September only.

Appendix 9C.

(19) Between what dates was the experiment conducted?	From February 24th to July 31st, 1897, and November 24th, 1897, to January 25th, 1900. Between these periods the bed was worked as a continuous filter.
If there were any periods of rest, state their duration.	
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	On certain occasions, when the bed showed signs of clogging, the filtrate appeared quite warm to the hand, as was also the interior of the bed, showing that rapid changes, possibly to some extent putrefaction, were going on.
(21) Was any nuisance caused by the experimental works?	No, although the filtrate sometimes smelt slightly of sulphuretted hydrogen.
(22) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(23) Give particulars of any other observations of importance which were recorded.	Towards the end of the experiment some difficulty was experienced in keeping the bed open, but the clogging did not extend below the upper foot.
(24) What inferences have been drawn from the experiment?	The good qualities of the filtrate obtained are attributed chiefly to the fine grade of the material, rather than to any specific action of the coal, though such an action, comparable for instance to the purifying effect of animal charcoal, is not regarded as impossible.
(25) If it is considered that it would e practicable to adopt this system for the disposa of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

Gilbert J. Fowler,
Signature of Officer under whose direction the experiment was conducted.

Form B. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Burnt Clay.

Name of authority - - - - - - -	Manchester.
Population of district - - - - - - -	500,000 at commencement to 550,000.
Water supply per head of the population - - -	gallons per day.
Estimated or measured dry weather flow of sewage -	19,500,000 (about) to 27,000,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	Yes.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc., F.I.C. (Supt.)
Name and qualification of chemist who has made the analyses.	W. Clifford, A.R.C. Sc. I. Edward Ardern, B.Sc. (Vict.) H. D. Bell, A. C. Oddie, E. Hadfield, } Junior Assistants. Under the direction of G. J. Fowler (Supt.)

(1) What was the nature of the chemical or chemicals used? — Lime and copperas.

(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?

1897	CaO 5·32	$FeSO_4 7H_2O$	5·29
1898	CaO 4·85	do.	5·34
1899	CaO 2·68	do.	2·24

(above numbers calculated on the average flow including storm water).

(3) State whether the chemicals were increased or decreased according to the nature and and volume of the sewage treated, and give particulars of any such variations.

(4) What is the capacity in gallons of the subsidence tanks? — 11 tanks. Total capacity, 12,375,000 gallons.

(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed. — 3,000 to 4,000 tons per week. About once a week.

(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent. — Continuous.

(7) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

(b) What was the depth of the bed? — 3 feet.

(c) What was the nature and size of the filtering material? — Burnt clay. 6 inches of coarse lumps at the bottom. 2 ft. 6 in., from ½ in. to 1 in.

(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Date.	Capacity in Galls.	Remarks.
Oct. 6th, 1897 ...	1,944	
Jan. 6th, 1898 ...	1,690	15 hours rest.
„ 7th, „ ...	1,680	„ „
June 20th, „ ...	1,674	1½ „
Oct. 11th, 1899 ...	1,260	1½ „
„ 16th, „ ...	1,656	Bed rested and forked over in meantime, 2½ hours rest.

(9) What was the water-holding capacity of the coarse beds at end of experiment?

If the measurement was made after resting, please give the duration of the resting.

Appendix 9C

Question	Answer
(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What was the nature and size of the filtering material?	
(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	See table below. During the latter period, one filling was omitted for a few weeks. In general, the cycle of operation was: (*a*) ½ hour, (*b*) 2 hours, (*c*) ½ hour, (*e*) remainder of day, according to the number of fillings.
(13) State by what method the settled sewage was distributed on the beds.	By means of wooden shoots, laid on the surface of the bed.
(14) What was the average quantity of sewage in gallons dealt with daily?	5,000 gallons per day, nearly.
(15) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.
(16) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Daily except Sundays. Samples shaken before analysis.
(17) Give (*a*) the average of the analyses of the final effluent from the beds;	The following numbers are the average of daily analyses during the whole period of working, from November 17th, 1897, to March 14th, 1900:—

Date.	No. of Fillings per day.	Time of Filling.
Nov. 17, 1897, to Dec. 8th, 1898...	3	8 a.m., 12 noon, & 4 p.m.
Dec. 16th, 1898, to Mar. 14th, 1900	4	8 a.m., 12 noon, 4 & 9 p.m.

Four Hours' Oxygen Absorption.	Incubator Test, 3 mins'. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.
	Before.	After.			
2·93	1·53	1·64	385½/645	1·62	0·14

Question	Answer
(*b*) the best analysis of the final effluent and date when sample was taken; and	
(*c*) the worst analysis of the final effluent and date when sample was taken;	
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	About 5·5 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Varying appreciable amounts not determined.
(18) Give a typical analysis of the crude sewage to which the experiment relates.	The following numbers are the average of daily analyses of *Settled Sewage* for the years 1898 and 1899:—

Date.	Four Hours' Oxygen Absorption.	3 mins. Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
Year 1898	7·36	3·75	2·27	0·37	16·2
1899	6·75	3·62	2·30	0·33	16·0

(19) Between what dates was the experiment conducted?	November 17th, 1897, to March 14th, 1900.
If there were any periods of rest, state their duration.	Every Sunday, and from July 23rd—August 11th, 1898. Total rest—140 days.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(21) Was any nuisance caused by the experimental works?	No.
(22) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(23) Give particulars of any other observations of importance which were recorded.	The bed required comparatively little raking or attention, remaining open for some considerable period of time. A large proportion of the filtrates were putrefactive. The material on being piled in heaps and exposed to the weather, recovers itself to a large extent, and it could be very readily washed.
(24) What inferences have been drawn from the experiment?	Burnt clay, such as is produced at Davyhulme, appears to be too slaty in fracture to form a good filtering medium, but it could probably be used satisfactorily for constructing storm-beds.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

GILBERT J. FOWLER,
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Red Sand Filter.

Name of authority	Manchester.
Population of district	430,764.
Water supply per head of the population	
Estimated or measured dry weather flow of sewage	17,230,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	New manufacturing district coupled up, just prior to this experiment.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc. (Vict.), F.I.C.
Name and qualification of chemist who has made the analyses.	H. D. Bell, junior assistant under G. J. Fowler.
(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	Cal. 5·32. $FeSO_47H_2O$ 5·29.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity, 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 tons a week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the bed when filled with the filtering material?	600 gallons.
(b) What was the depth of these beds?	3 feet.
(c) What was the nature and size of the filtering material?	6 inches of hard red sandstone rock at the bottom, 2 feet 6 inches of fine red sand.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	
(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(b) What was the depth of these beds?	
(c) What was the nature and size of the filtering material?	
(11) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	

Appendix 9C.

(12) State method of working of contact bed, *i.e.*, the number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	First week - - - - - 2 fillings per day. Second week - - - - - 2 or 3 fillings per day. (*a*) $\frac{1}{2}$ hour. (*b*) 2 " (*c*) $\frac{1}{2}$ " (*e*) 18 "
(13) State by what method the settled sewage was distributed on the beds.	By means of wooden shoots laid on the surface of the bed.
(14) What was the average quantity of sewage in gallons dealt with daily?	1,500 gallons per day.
(15) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Daily except Sundays. Shaken.
(17) Give (*a*) the average of the analyses of the final effluent from the beds;	4 hours oxygen absorption - - 1·24 Ammoniacal nitrogen - - - ·86 Albuminoid nitrogen - - - ·09 All samples non-putrescent.
(*b*) the best analysis of the final effluent and date when sample was taken; and	
(*c*) the worst analysis of the final effluent and date when sample was taken;	
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	About 55 pints per 100,000
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Nil.
(18) Give a typical analysis of the crude sewage to which the experiment relates.	Average of analyses of *Settled Sewage* during time of experiment: 4 hours Oxygen absorption - - 9·13 Ammoniacal Nitrogen - - - 2·38 Albuminoid Nitrogen - - - ·42
(19) Between what dates was the experiment conducted?	May 20th to June 3rd, 1897.
If there were any periods of rest, state their duration.	Rested on Sundays.
(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(21) Was any nuisance caused by the experimental works?	No.
(22) Is the experiment still proceeding?	
If so, may the Commission inspect the works, should they deem it desirable to do so?	No
(23) Give particulars of any other observations of importance which were recorded.	The sand rapidly silted up, so that the experiment was abandoned at the end of a fortnight.
(24) What inferences have been drawn from the experiment?	That the sand used was unsuitable for filtering the tank effluent.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

GILBERT J. FOWLER.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Rough Cinder Bed.

Name of authority	Manchester.
Population of district	550,000.
Water supply per head of the population	Domestic use, 17; trade purposes, 11. 28 gallons per day.
Estimated or measured dry weather flow of sewage	27,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Breweries, dye and bleach works, galvanising works, grease refineries, tanneries, manufactories of tar products, rubber goods works, tripe-dressing works, mineral water manufactories. 4 to 5 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm-overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1. In certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc., F.I.C., Superintendent. W. Clifford, A.R.C.Sc.I. Edward Ardern, B.Sc. (Vict.) H. D. Bell, A. C. Oddie, E. Hadfield, } Junior Assistants.
Name and qualification of chemist who has made the analyses.	Under the direction of G. J. Fowler, Superintendent.

(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	CaO 2·68. $FeSO_4 7H_2O$ 2·24 (Calculated on the average flow, including storm water.)
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Addition of chemicals suspended altogether in case of heavy storm and latterly often in the early hours of the morning when the sewage is dilute. The addition of chemicals is regulated at other times by (1) the character of the precipitate produced in a test-glass, and (2) the reaction with phenol phthalein. The amount of lime has to be increased considerably during the presence of acid waste or iron pickle, as much as *24 grains CaO* per gallon being added; the amounts of both lime and copperas have to be increased in presence of dye waste, as much as *29 grains CaO.* and *12 grains copperas* being added.
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity, 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000—4,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(*b*) What was the depth of this bed?	15 inches.
(*c*) What was the nature and size of the filtering material?	Unscreened clinker. All sizes up to 6 inches. Underdrains formed by grips cut into the surface of the land, filled with broken bricks.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Exact measurements were not practicable, but the time occupied in filling has remained practically constant (with the same flow), during the last 12 months.
(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	

10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(b) What was the depth of these beds?

(c) What was the nature and size of the filtering material?

(11) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting.

Method of working coarse cinder bed.

Date.	No. of fillings per day.	Time of filling.
June 27th to Sept. 7th, 1899.	2	8 a.m. & 12 noon.
Sept. 7th, 1899 to Mar. 8th, 1900.	3	8 a.m., 12 noon & 4 p.m.
March 8th to May M30th, 1900.	4	8 a.m., 12 noon, 4 p.m., & 9 p.m.
ay 31st up to present time.	2 ordinary fillings No. of fillings increased in time of storm.	8 a.m. and 12 noon

In general the cycle of operations has been as follows:—(a) 20 minutes, (b) 2 hours, (c) ½ hour, and (e) remainder of 24 hours according to the number of fillings.

In the case of treatment of storm water, the time of contact is reduced to 1 hour.

The bed always rested on Sundays.

(13) State by what method the settled sewage was distributed on the beds.

By means of one large penstock, immediately beneath which a few sett stones were placed to receive the full force of the water, which then found its way over and into the bed without further direction.

(14) What was the average quantity of sewage in gallons dealt with daily?

33,500 gallons per day (including storm water).

(15) Was the quantity of sewage dealt with increased in time of storm?

Yes latterly, the increased amount dealt with varying with the dilution of the sewage, the number of contacts first being increased and finally the sewage is allowed to stream through the bed.

If so, state to what extent, and how the results were affected by such increase.

The maximum quantity of sewage thus dealt with being equal to 24 fillings per day.

In the majority of cases the filtrate was non-putrefactive, and the excessive rate of working does not cause any subsequent ill effects.

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily except Sundays.

Samples shaken before analysis.

(17) Give (a) the average of the analyses of the final effluent from the beds;

The following numbers are the averages of daily analyses of (1) from June 27th, 1899, to May 30th, 1900, during which period the bed has been worked up from 2 to 4 fillings per day. (2) From June 13th to December 26th, 1900, during which period the bed has received 2 fillings per day in dry weather, the number of fillings being increased in time of storm.

Date.	Four Hours.	Incubator Test—3 min. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
		Before.	After.						
June 27th 1899 to May 30th, 1900	2·70	1·53	1·60	137½/277	1·38	·108	·028	·234	15·4
* June 13th, 1900, to Dec. 26th, 1900	2·41	1·36	1·11	10/119	1·14	·121	·043	·25	14

* Figures for this period for four hours oxygen absorption, nitrogen determinations and chlorine refer to the analysis of daily sample from May 31st to August 8th only. The figures for the incubator test are the average of daily analyses during the whole period.

(b) the best analysis of the final effluent and date when sample was taken; and

(c) the worst analysis of the final effluent and date when sample was taken;

(d) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

About 5·5 parts per 100,000. In case of storm this amount is increased. In certain cases it was estimated at 17 parts per 100,000.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Small amount suspended matter. Actual amount not determined.

Appendix 9C.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily samples of *settled sewage* for the year 1899 and half-year ending June 27th, 1900, and of crude sewage for the half-year ending December 26th, 1900.

Date.	Four Hours Oxygen Absorption.	Three Minutes Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
January to December, 1899. (Settled sewage.)	6·75	3·62	2·30	·33	16·0
January to June 27th, 1900. (Settled sewage.)	7·86	3·93	1·91	·335	16·3
June 27th to Dec. 26th, 1900. (Crude sewage.)	11·11	5·49	2·23	·590	17·0

(19) Between what dates was the experiment conducted? — From June 27th, 1899.

If there were any periods of rest, state their duration. — Every Sunday, and from May 30th to June 13th, 1900. Total rest = 80 days.

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

(21) Was any nuisance caused by the experimental works? — No.

(22) Is the experiment still proceeding? — Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so? — Yes.

(23) Give particulars of any other observations of importance which were recorded.

It was noted that although the filter had an earth bottom, and was surrounded on three sides by earth banks, very little leakage took place after the bed had been a short time in use. The tank effluent being admitted at one spot, such clogging as took place was immediately surrounding the inlet, the further portions of the filter still appear to be practically clean.

On exposing the soil bottom, a thin black film of iron sulphide was found to have formed, but this does not apparently tend to pollute the filtrate.

During the 18 months the bed has been at work, it has only been once necessary to run a light harrow over it.

It appears that beds for the purification of storm water, may be cheaply and effectively constructed after the model of the bed here described.

(24) What inferences have been drawn from the experiment

It is important only that the clinkers should be well burnt, and the fine portions sharp, so that they do not tend to set together. Such a bed should be capable of receiving one or two fillings a day of settled sewage, in fine weather, with a good result, and in time of storm the number of fillings may be increased to an almost unlimited extent in proportion to the dilution of the sewage.

(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers?

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan?

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

GILBERT J. FOWLER,
Signature of Officer under whose direction the experiment was conducted.

Form C.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Carbonaceous Iron Sand Filter.

Name of Authority	Manchester.
Population of district	550,000.
Water supply per head of the population	Domestic use, 17 ; trade purposes, 11. 28 gallons per day.
Estimated or measured dry weather flow of sewage	27,000,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enters the sewers. Storm overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1. In certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted.	Gilbert J. Fowler, M.Sc., F.I.C. (Supt.).
Name and qualification of chemist who has made the analyses.	Edward Ardern, B.Sc. (Vict.). H. D. Bell, A. C. Oddie, E. Hadfield } Junior Assistants. Under the direction of G. J. Fowler (Supt.).
(1) What was the nature of the chemical or chemicals used.	Line and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	CaO 2·5, $FeSO_4 7H_2O$ 2·0.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of such variations.	
(4) what is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity, 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 to 4,000 tons per per week. About once a week
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent	Continuous.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(*b*) What was the depth of this bed?	2 feet 6 inches.
(*c*) What was the nature and size of the filtering material?	Carbonaceous iron sand, consisting of fine screenings from iron waste heaps, composed chiefly of oxide of iron, silic and a small proportion of carbon. Six inches of rubble at the bottom, then 2 feet of fine carbonaceous iron sand.

(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Date.	Capacity in Gallons.	Remarks.
March 14th, 1900	1,000	3 hours draining
April 3rd	936	3¾ „ ,
June 29th	1,044	2½ „ „

(9) What was the water-holding capacity of the coarse beds at end of experiment?

If the measurement was made after resting, please give the duration of the resting.

Appendix 9C.

(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of these beds? - - -

(*c*) What was the nature and size of the filtering material?

(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

(12) State method of working of contact bed, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

1900. January 29th—March 14th, bed filled at 8 a.m. Cycle, (*a*) ½ hour; (*b*) 2 hours; (*c*) ½ hour; (*e*) 1 hour. Then 3 flushes of tank, effluent (exit valve open) between 12 noon and 4 p.m., 1 filling. Total quantity dealt with = 2 fillings per day.

March 15th—July 11th. As above, with additional filling at 9 p.m. Cycle, (*a*) ½ hour; (*b*) 2 hours; (*c*) ½ hour; (*e*) 8 hours. Total quantity dealt with = 3 fillings per day.

(13) State by what method the settled sewage was distributed on the bed.

By means of wooden shoots laid on the surface of the bed.

(14) What was the average quantity of sewage in gallons dealt with daily.

1,970 gallons per day.

(15) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily, except Sundays. Sample shaken before analysis.

(17) Give (*a*) the average of the analyses of the final effluent from the beds.

The following numbers are the average of daily analyses of the filtrate from the bed during the whole period of working:—

Four Hours Oxygen Absorption.	Incubator Test—3 mins. Oxygen Absorption. Before.	Incubator Test—3 mins. Oxygen Absorption. After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitrico Nitrogen.	Chlorine.
	·61	·50	0/137	1·55	·061	·082	·61	15·6

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

About 5 to 6 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Nil.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of *Settled Sewage* for the half-year ending June 27th, 1900:—

Four hours Oxygen Absorption.	Three minutes Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
7·86	3·93	1·91	·335	16·3

(19) Between what dates was the experiment conducted?

January 29th to July 11th, 1900. Every Sunday, and from June 16th to June 28th.

If there were any periods of rest, state their duration.

Total rest—34 days.

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

Appendix 9C.

(21) Was any nuisance caused by the experimental works.	No.
(22) Is the experiment still proceeding?	
If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(23) Give particulars of any other observations of importance which were recorded.	The sand was found to be very heavy and the surface tends to set, so that very frequent raking is necessary.
(24) What inferences have been drawn from the experiment?	Under the conditions of the experiment, the material appeared to receive too great an amount of suspended matter. Judging, however, from the excellent quality of the filtrate obtained, it seems likely that the material is capable of dealing with a liquid containing but little suspended impurity, *e.g.*, well clarified tank-effluent or filtrate from primary beds.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

Gilbert J. Fowler.
Signature of officer under whose direction the experiment was conducted.

Appendix 9C. Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

CINDER SCREENINGS BED.

Name of Authority	Manchester.
Population of District	550,000.
Water Supply per head of the population	Domestic use - 17, Trade purposes, 11 } 28 gallons per day.
Estimated or measured dry weather flow of sewage	27,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Breweries, dye and bleach works, galvanising works, grease refineries, tanneries, manufactories of tar products, rubber goods works, tripe dressing works, mineral water manufactories.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	4 to 5 per cent. mostly enter the sewers. Storm overflow are provided at certain points which are supposed to come into action at a dilution of 5 to 1, in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc.; F.I.C. (Supt.) Edward Ardern, B.Sc. (Vict.) H. D. Bell, A. C. Oddie, E. Hadfield, } Junior assistants.
Name and qualification of chemist who has made the analyses.	Under the direction of G. J. Fowler (Supt.)

(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	CaO 2·5 $FeSO$ 4·7 H_2O 2·0
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity, 12,375,000.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 to 4,000 tons per week. About once a wee
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(b) What was the depth of these beds?	2 feet 6 inches.
(c) What was the nature and size of the filtering material?	Ordinary clinker screenings which have passed through a $\frac{1}{8}$-inch mesh; 6 inches at bottom of bed rough clinker, 2 feet screenings.
(8) Give particulars of measurements made from time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	(see table below)

Date.	Capacity in Gallons.	Remarks.
April 3rd, 1900	1,260	$2\frac{1}{2}$ hours draining.
June 29th, 1900	1,224	$2\frac{1}{2}$ ours draining.
January 7th, 1901	1,332	3 days' rest.

(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(b) What was the depth of these beds?	
(c) What was the nature and size of the filtering material?	

(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

(12) State method of working of contact bed, *i.e.* number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

March 21st—April 12th, 1900.
1 filling (*a*) ½ hour, (*b*) 2 hours, (*c*) ½ hour, (*e*) 1½ hours.
Then 2 flushes of tank-effluent between 12 noon and 4 p.m. = to 1 filling.
Thus the amount dealt with = 2 *fillings per day*.
April 13th—December 26th, 1900.
As above, with an extra filling at 9 p.m., cycle (*a*) ½ hour, (*b*) 2 hours, (*c*) ½ hour, (*e*) 8 hours.
Total amount dealt with = 3 *fillings per day*.

13) State by what method the settled sewage was distributed on the beds.

By means of wooden shoots laid on the surface of the bed.

(14) What was the average quantity of sewage in gallons dealt with daily?

2,570 gallons per day.

(15) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily except Sundays. Samples shaken before analysis.

17) Give (*a*) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses during the whole period from March 21st—December 26th.

Date.	Four Hours Oxygen Absorption.	Incubator Test 3 min. Oxygen Absorption.		Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine
		Before.	After.						
March 21st to Dec. 26th 1900.*	1·16	·57	·43	0/190	0·93	0·069			16·1

* The figures for 4 hours oxygen absorption, nitrogen determinations and chlorine represent the average of daily analyses from March 21st—August 1st. The incubator test figures are the average for the whole period.

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

About 5 to 6 parts per 100,000.

e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Nil.

( ) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of Crude Sewage for the half-year ending December 26th, 1900:—

Four Hours Oxygen Absorption.	3 minutes Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
11·11	5·49	2·23	0·59	17·0

(19) Between what dates was the experiment conducted?

Commenced March 21st, 1900, still proceeding.

If there were any periods of rest, state their duration.

Total rest (including Sundays), 74 days.

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

(21) Was any nuisance caused by the experimental works?

No.

(22) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Appendix 9C.

(23) Give particulars of any other observations of importance which were recorded.

It was found that in spite of its fine grade that the material remained open for a considerable time, raking being necessary about once a month.

The surface has been removed to the depth of about four inches and the material piled in heaps on the surface of the beds. On the second occasion the heaped material was put back in place of that which was removed. In this way it appears possible to prolong the life of a bed for a very considerable period. Recently the experiment has been tried of running the slurry obtained by washing the adjacent cinder filter on to the surface of the bed in question, in order to see if the mud would drain and be capable of removal from the surface of the bed, without injury to the medium. So far as this experiment goes it appears quite practicable to do this, and the experiment has its bearing on a choice of a method of washing the beds, should this at any time be necessary.

(24) What inferences have been drawn from the experiment?

The experiment indicates that the screenings from clinkers, which otherwise would be waste products, may be largely employed in covering the surface of contact beds, serving to arrest suspended matters, thus protecting the lower portions of the filter and forming an active nitrifying layer on the surface.

(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note 1.—It is requested that all analyses may be stated in parts per 100,000 and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminiod nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

GILBERT J. FOWLER.

Signature of officer under whose direction the experiment was conducted.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS AFTER CHEMICAL PRECIPITATION.

Spent Iron Ore Bed.

Name of Authority - - - - - - -	Manchester.
Population of District - - - - - - -	550,000.
Water Supply per head of the population - - -	Domestic use 17, Trade purposes 11 } 28 gallons per day.
Estimated or measured dry weather flow of sewage -	27,000,000 gallons per day.
Is any trade refuse taken into the sewers? - - -	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made of trade refuse.	
Is the storm, soil or surface water, wholly or partially. excluded from the ordinary sewers?	Mostly enter the sewer.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M. Sc., F.I.C. (Supt.) Edward Ardern, B.Sc. (Vict.) H. D. Bell, A. C. Oddie, E. Hadfield. } Junior Assistants.
Name and qualification of chemist who has made the analyses.	Under the direction of G. J. Fowler (Supt.)
(1) What was the nature of the chemical or chemicals used?	Lime and Copperas.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	Ca O 2·5. Fe. So_4 4·7 H_2O. 2·0.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	—
(4) What was the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 to 4,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(b) What was the depth of these beds?	3 feet.
(c) What was the nature and size of the filtering material?	Spent iron ore. 6in. large lumps at bottom, 2 feet coarse material (about 1in.) 6in. fine material which has passed through $\frac{1}{8}$in. mesh.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	see table below
(9) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	
(10) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(b) What was the depth of these beds?	
(c) What was the nature and size of the filtering material?	

Answer to (8):

Date.	Capacity in Gallons.	Remarks.
January 7th, 1901	1,548	2 days' rest.

Appendix 9C.

(11) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying and (e) resting.

Date.	No. of fillings per day.	Time of filling.
Aug. 25 to Jan. 17	2	8 a.m. to 12 noon.
1901	3	8 a.m., 12 & 9 p.m.

(a) ½, (b) 2 hours, (c) ½ hour, (e) remainder of time.

(13) State by what method the settled sewage was distributed on the beds.

By means of wooden shoots laid on the surface.

(14) What was the average quantity of sewage in gallons dealt with daily?

(15) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(16) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily except Sunday. Samples shaken before analysis.

(17) Give (a) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses from Aug. 25—Dec. 26, 1900.

Oxygen Absorption. Four Hours.	Three Minutes. Oxygen Absorption. Before. Incubator.	After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
2·31	1·59	1.43	6½/98	1·97	·109	·051	·030	16·4

(b) the best analysis of the final effluent and date when sample was taken, and

The figures for four hours' oxygen absorption, nitrogen determinations and chlorine refer to average from September 13th to October 10th, 1900.

(c) the worst analysis of the final effluent and date when sample was taken;

(d) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

About 5 to 6 per 100,000.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Slight.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of Crude Sewage for the quarter ending December 26th, 1900.

Four hours Oxygen Absorption.	3 mins. Oxygen Absorption.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.
11·46	5·47	2·01	0 61	16·6

(19) Between what dates was the experiment conducted?

Commenced August 28th, 1900—still proceeding.

If there were any periods of rest, state their duration.

Every Sunday and from December 6th to 13th. Filling occasionally missed at week ends.

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

(21) Was any nuisance caused by the experimental works?

No.

(22) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Appendix 9C.

(23) Give particulars of any other observations of importance which were recorded.	Owing to the fineness of the material on the surface and its tendency to bind together, the bed soon became tight and took the water very slowly, thus requiring frequent attention. On December 17th, 1900, the top 3 inches were removed, after which the bed worked considerably better as regards clogging of surface.
(2) What inferences have been drawn from the experiment ?	The special character of the material apparently offered no particnlar advantage, as there was little nitrification and the samples were sometimes putrescent, even with only 2 fillings per day.
(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state (a) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers. (b) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen ;

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

GILBERT J. FOWLER.

Signature of officer under whose direction the experiment was conducted.

Appendix 9C.

Form C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT) AFTER CHEMICAL PRECIPITATION.

Name of authority	Oldham Corporation.
Population of district	155,865.
Water supply per head of the population	22½ gallons per day.
Estimated or measured dry weather flow of sewage	4,000,000 gallons per day (estimated).
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes. Small quantities of tripe boiling refuse, brewing refuse, dye-water refuse, and foul water, from lodges of cotton mills; this latter is the worst we have to deal with, but the total quantity of trade refuse is a negligeable quantity.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially excluded. Over ¼-inch rainfall.
Officer under whom the experiment has been conducted	Dr. James B. Wilkinson, Medical Officer of Health.
Name and qualification of chemist who has made the analyses.	A. S. Wylie.
(1) What was the nature of the chemical or chemicals used?	Lime water and ferrous sulphate (green copperas).
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	Lime water, 4 grains per gallon. Ferrous sulphate, 1 grain per gallon.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Yes, quantity increased or decreased according to volume of sewage by means of automatic machinery, designed by Mr. H. H. Law.
(4) What is the capacity in gallons of the subsidence tanks?	2,116,800 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	Unable to state the weekly quantity as each tank was working on an average 3 months before it was cleaned out, at the end of that time there was a depth of about 2 ft. 4 in. of sludge in each tank; about 10,500 cubic feet of wet sludge.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Cubic capacity estimated at 40 per cent.
(*b*) What was the depth of these beds?	2 ft. to 2 ft. 9 in.
(*c*) What were the nature and size of the filtering material?	All the filters were made of furnace clinkers. All pieces which passed through a ¼-inch screen were rejected. Material was not graded in the filters.
(8) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No observations made
(9) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(10) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(11) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(12) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Each bed was filled twice in 24 hours. (*a*) filling—½ to ¾ of an hour. (*b*) standing full—2 hours. (*c*) emptying—about 2 hours. (*e*) resting—interval between 1st and 2nd filling 2 hours at least.
(13) State by what method the settled sewage was distributed on the beds.	Distributed over beds by means of wooden carriers.

Appendix 9C.

(14) What was the average quantity of sewage in gallons dealt with daily?

484,000 gallons per acre.

(15) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(16) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Samples were taken daily, were analysed the day following. Samples were *not* filtered through filter paper, and were *not* allowed to clear by standing. Each sample was well shaken before being analysed.

(17) Give (*a*) the average of the analyses of the final effluent from the beds.

·91 of a grain of oxygen per 100,000 absorbed in 4 hrs. test.
1·9 " " " ammoniacal nitrogen.
·197 " " " albuminoid nitrogen.
8·57 " " " chlorine.

(*b*) the best analyses of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

June 22nd, 1898.

Oxygen absorbed 4 hours.	Ammoniacal nitrogen.	Albuminoid nitrogen.	Chlorine.
·21	1·01	·16	7·1
July 20th, 1898.			
3·44	5·34	·55	10·5

All estimated as parts per 100,000.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

None made.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Of 90 samples that were incubated 50 kept good, and 40 were putrescible. No estimations were made of solids in suspension in the final effluents.

(18) Give a typical analysis of the crude sewage to which the experiment relates.

Oxygen absorbed 4 hours.	Ammoniacal nitrogen.	Albuminoid nitrogen.	Chlorine.
4·53	4·0	1·1	13·4

parts per 100,000.

(19) Between what dates was the experiment conducted?

From beginning of 1897 to end of 1898.

If there were any periods of rest, state their duration

Yes. Filters rested every Sunday, and also periods of two to three weeks when necessary.

(20) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

None made.

(21) Was any nuisance caused by the experimental works?

No.

(22) Is the experiment still proceeding? - - - - -

No.

If so, may the Commission inspect the works, should they deem it desirable to do so?

(23) Give particulars of any other observations of importance which were recorded.

(24) What inferences have been drawn from the experiment?

The sewage of Oldham can be effectively purified without using chemicals as an aid to precipitation.
That the chemicals are an unnecessary expense, and, rather hinder the work of the bacteria beds than assist it. It is necessary, however, to add lime to the sludge to enable it to be pressed.

(25) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

See answer to 24.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

JAMES B. WILKINSON, M.D, C.M., D.P.H.
Signature of Officer under whose direction the experiment was conducted.
Medical Officer of Health.

Appendix 9C .Form D.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS.

Name of authority	Ashton-in-Makerfield U. D. Council.
Population of district	(Estimated) 20,000.
Water supply per head of the population	8 to 10 gallons per day.
Estimated dry weather flow of sewage	8 water supply. 2 other sources. 3 subsoil. — 13 to 15 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No trade refuse dealt with in the districts under notic . Population, coal mining industry.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	In the districts dealt with storm water from roads and roofs partially is allowed in sewers. So subsoil water also gets in. In the district generally both storm, subsoil and surface water are carried by separate surface water drains.
Officer under whom the experiment has been conducted	John W. Liversedge, Surveyor.
Name and qualification of chemist who has made the analyses.	

(1) What is the capacity in gallons of the subsidence tanks?	Constructed July, 1900. 18ft. by 6ft. by 2ft. 6ins. deep. Capacity 1,600 gallons.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	No actual measurements have been taken. The amount of dry sludge barrowed from the works since July, 1898, to the present, has been about 8 tons in addition to the sludge in the body of the beds.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous flow.
(4) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	No actual measurement of such capacity was taken. I estimated the water capacity at half the cubic contents of the rough cinders, or total holding capacity level to bed of cinders, 31,500 gallons.
(b) What was the depth of these beds?	3ft. 6in. to 4ft. for first contact, or average depth, 3ft. 9in. Second contact—3ft. to 3ft. 6in., average, 3ft. 3in.
(c) What was the nature and size of the filtering material?	Hard cinder clinker from local collieries. First contact, all clinker retained on 1in. screen, large pieces broken to 3in. or 4in.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No experiments have taken place, but from personal observation reducing has taken place. In fact, I have during the past fortnight considered it advisable to have 8 ins. of cinders, the top layer, taken off and screened on 1-in. screen, the rough cinders put back, and the detritus removed. New cinders added to make up the depth. Owing to the surface water getting into the sewers quantities of road grit found its way into the beds, previous to putting down the subsidence tank, and at present the small tank down is not adequate to effect proper preliminary subsidence.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	No experiments.
(7) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	(Estimated) 26,000 gallons.
(b) What was the depth of these beds?	3 ft. to 3 ft. 6 in., average 3 ft. 3 in.
(c) What was the nature and size of the filtering material?	All cinders passed through the 1i-n. screen.

Appendix 9C.

(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	No experiments conducted.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	No direct experiment has been conducted, but from observation it would appear that the fine beds in the works under notice did not diminish in capacity as the rough beds referred to.
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Number offillings, 1, 2, or 3, depends on dry or wet weather flow. First Contact.—(*a*) filling, dry weather, 8 hours to 10 hours, (*b*) 2 hours to 4 hours, (*c*) 2 hours to 4 hours, (*e*) 8 or 12 hours, sometimes 16 hours; these times are halved or further reduced in periods of rain. Second Contact.—Effluent from first contact is spread over as great an area as possible, and percolates gently through the fine cinders; better results were perceived by this system than by closing the outlet valve and filling the bed full, with emptying and resting periods. The aeration of the bed seemed more complete.
(10) State by what method the settled sewage was distributed on the beds.	By means of half-pipes, stoneware, run diagonally and across the beds, and changed from time to time.
(11) What was the average quantity of sewage in gallons dealt with daily?	Dry weather 12,000 to 16,000 gallons, wet weather 25,000 to 50,000 gallons and over; the latter quantities imperfectly dealt with.
(12) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	The result of admitting storm water has the effect of chilling the beds and rendering less active the bacteria, and better results are noticed from crude sewage with high temperature than from diluted sewage by storm water. I do not think more than 3 or 4 times the dry weather flow should be put through crude sewage beds, but that land or separate storm beds would be advisable.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	
(14) Give (*a*) the average of the analyses of the final effluent from the beds;	
(*b*) the best analysis of the final effluent and date when sample was taken; and	
(*c*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(15) Give a typical analysis of the crude sewage to which the experiment relates.	No analysis.
(16) Between what dates was the experiment conducted?	July, 1898, to the present time.
If there were any periods of rest, state their duration.	Short periods of rest in summer; each bed about one month.
(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	The beds have not been affected by frost—that is, the working has not been discontinued. No notes of temperature have been taken. But greater activity of insect life and better effluent have been noticed in summer than winter.
(18) Was any nuisance caused by the experimental works?	No; no complaints whatever. The effluent passing from the works has passed into the brook, and been used for steam-generating purposes. There has been some slight smell noticeable since the small subsidence tank was laid down; before no smell was perceptible.
(19) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	he works are still in operation, and I feel sure my Council would offer your Commission every facility if you thought it desirable to inspect the works.

Appendix 9C.

(20) Give particulars of any other observations of importance which were recorded.	I consider it desirable: 1. That a preliminary subsidence chamber and tanks be constructed to prevent grit and paper and solids getting on the surface of the beds and clogging them. 2. That storm water should be limited as far as possible from passing into beds which are intended to break up and liquefy solids, as the cool water has the effect of retarding the action of the beds, and that fine cinder filters or land for this purpose might with advantage be used. The beds work better after the season of rest. A black effluent from the first series will give a clear effluent from the second series, whereas a milky effluent from first gives often a milky effluent from second. The effluent in winter not quite so good as in summer. The fine beds should not have material of less mesh than ¼ in. 1 inch to ¼ inch works satisfactory.
(21) What inferences have been drawn from the experiment?	That it is not absolutely necessary to construct expensive concrete and brick beds where clay land is obtainable except for the detritus or settling tanks. The works, including Lowe Bank and Garswood, which deal with population of 2,500, cost £450, were constructed out of current rate. Of this amount, £150 was spent in wrought iron fencing and £20 in roads, leaving nett cost of works at £280. The results arrived at have encouraged my Council to extend the system, and beds of a similar nature have been constructed, to deal with a population of 10,000, and for which purpose 1¼ acres of beds have been provided, the cost of which will be £1,100, ; these beds will be working in the course of one month and no sewage has yet been put through them. An area of land is being provided at Garswood and Lowe Bank for storm water, and steps are being taken to take out all the storm water possible from the sewers.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes, if required.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	£110 per 1,000 of population, or, say 2s. 6d. per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	One man could look after works dealing with a population of 1,000, with slight help at times. One man would be required to attend on smaller works, which would increase the cost. It has cost for maintenance £60 per annum for Lowe Bank and Garswood Works, or about 6d. per head of population per annum.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tank" is intended to denote tanks which are used so that little or no "Septic" action is produced.

John W. Liversedge, Surveyor.
Signature of Officer under whose direction the experiment was conducted.

Form D.

Appendix 9C

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority	Burgess Hill Urban District Council.
Population of district	5,000.
Water supply per head of the population	18 gallons per day.
Estimated or measured dry weather flow of sewage	About 100,000 gallons per day.
Is any trade refuse taken into the sewers?	No.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Only partially excluded.
Officer under whom the experiment has been conducted	Surveyor E. Brown.
Name and qualification of chemist who has made the analyses.	R. A. Cripps, F.I.C.
(1) What is the capacity in gallons of the subsidence tanks?	750 gallons.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	Usually filled in a week and emptied in a week.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous when used. The tanks are in duplicate and one is in use while the other is emptied.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	No coarse beds.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	
(6) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	
(7) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	9,000 gallons.
(*b*) What was the depth of these beds?	3 ft. 6 in. deep.
(*c*) What were the nature and size of the filtering material?	Mainly furnace clinkers, some coke passed through a $\frac{1}{8}$-in. screen and rejected by a $\frac{1}{2}$-in. screen.
(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	This has not been done, but the capacity is very little reduced in six months' use.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Not been measured.
(9) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Worked automatically, average time of filling two hours, and worked in a set of four beds, each bed filled three times per day. (*a*) Average - - 2 hours. (*b*) „ - - 2 „ (*c*) „ - - $1\frac{1}{2}$ „ (*e*) „ - - $2\frac{1}{2}$ „
(10) State by what method the settled sewage was distributed on the beds.	Distributed by automatic gear through valves, pipes and channels.
(11) What was the average quantity of sewage in gallons dealt with daily?	About 100,000 gallons.
(12) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	More than doubled, but the results remain about the same, dilution of sewage compensates for the increase of flow.

Appendix 9C.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Only one analysis has been taken. No.
(14) Give (*a*) the only analysis of the final effluent from the beds.	Total solids - - - - - 81·42 parts per 100,000. Solids in suspension - - - 2·14 " " " Chlorine - - - - - 11·85 " " " Ammonia (N as) - - - 3·85 " " " Albuminoid ammonia - - ·24 " " " Oxygen absorbed in three hours ·554 " " " Nitrites - - - - - - very large traces. Nitrogen as nitrates - - ·447 parts per 100,000.
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the farm.	101·42.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	2·14. No evidence.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	Total solids - - - - - 172·14 parts per 100,000. Solids in suspension - - 101·42 " " " Chlorine - - - - - 11·28 " " " Ammonia (as N) - - - 17·20 " " " Albuminoid ammonia - - 4·00 " " " Oxygen absorbed in three hours 8·03 " " " Nitrites - - - - - absent. Nitrogen as nitrates - - - "
(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	Beds have been working continuous for four months previous to the analysis being made.
(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	Was not taken, but notices effluent was often brighter on bright sunshiny days.
(18) Was any nuisance caused by the experimental works?	None.
(19) Is the experiment still proceeding? - - - - If so, may the Commission inspect the works, should they deem it desirable to do so?	The beds are still in use. Yes.
(20) Give particulars of any other observations of importance which were recorded.	These beds are used as a supplemental treatment to a clay sewage farm. It has been found that in summer or very dry weather the clay cracks and the purification was very imperfect, and the stream into which the effluent discharged became polluted, but since the introduction of the bacteria beds, through which all the effluent from the farm passes, the stream has been cleansed, and little, if any, evidence is now seen that a sewage effluent discharges into the stream.
(21) What inferences have been drawn from the experiment?	Up to the present date we have found the beds effect all that was expected, and we propose to continue them in connection with the sewage farm.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	The whole of the sewage is treated by this system.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	The beds cost 725*l*.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	No calculations made.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended o denote tanks which are used so that little or no "Septic" action is produced.

EDW. BROWN,
Signature of Officer under whose direction the experiment was conducted.

Appendix 90.

Form D.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS.
(SINGLE CONTACT.)

Name of authority	Corporation of Croydon.

The following replies relate to South Norwood Farm only :—

Population of district	21,000 draining to this farm.
Water supply per head of the population	25 gallons per day.
Estimated dry weather flow of sewage	600,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Very little, excepting from slaughter-houses.
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted	Mr. John Figg, the Farm Manager.
Name and qualification of chemist who has made the analyses.	Mr. Farmer, the Corporation Farm Analyst.

(1) What is the capacity in gallons of the subsidence tanks?	The open outfall sewers on the farm through which the sewage passes to the contact beds, and usually have about 25,000 gallons of sewage in them slowly passing to the beds.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	About one cube yard a week, which is removed monthly.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(4) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	From a test made in a measure by filling water into the ballast it held 50 per cent. of water.
(b) What was the depth of these beds?	3 ft. 10 in.
(c) What were the nature and size of the filtering material?	Burnt ballast rejected by a sieve with inch mesh.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No measurements have been taken; the level of the beds is too high to do this with any accuracy.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	No particulars taken.
(7) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No fine beds constructed.
(b) What was the depth of these beds?	
(c) What were the nature and size of the filtering material?	
(8) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Two fillings in 24 hours, but on Sundays only one filling. Times: (*a*) $1\frac{1}{3}$ hours, (*b*) 2 hours, (*c*) $1\frac{1}{3}$ hours, (*e*) $2\frac{1}{3}$ hours.
(10) State by what method the settled sewage was distributed on the beds.	By earthenware half-pipes on the top of the beds.
(11) What was the average quantity of sewage in gallons dealt with daily?	About 450,000 gallons

Appendix 9.

(12) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase.

No. At such times storm water passes through other sedimentary tanks, and then over the land by broad irrigation.

(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Analyses of the effluent are made weekly from one bed in rotation, and they are shaken before analyses.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

(*b*) the best analysis of the final effluent, and date when sample was taken; and

(*c*) the worst analysis of the final effluent, and date when sample was taken;

—	Oxygen absorbed		Chlorine.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Date.
	¼ hour.	4 hours.				
(*a*)* -	1·15	2·18	8·5	2·13	0·32	—
(*b*)* -	0·41	0·92	5·7	0·36	0·12	Nov. 2, 1899.
(*c*)* -	1·11	2·73	8·5	3·6	0·54	Dec. 24, 1900.

* Coarse bed.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

42·8.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

5·7. Sometimes slightly.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Oxygen absorbed.		Chlorine.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.
¼ hour.	4 hours.			
3·82	7·01	8·7	8·09	1·01

(16) Between what dates was the experiment conducted?

If there were any periods of rest, state their duration.

The experimental bed has been in constant use since April 16th, 1898, with three partial rests of a fortnight each, when the bed was filled once a day instead of twice.

The other five beds have been in use from one to six months without a rest.

(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

None taken.

(18) Was any nuisance caused by the experimental works?

None.

(19) Is the experiment still proceeding? - - - -

If so, may the Commission inspect the works, should they deem it desirable to do so?

Permanent works have been constructed for three-fourths of the dry-weather flow. The works can be seen any time without any notice.

(20) Give particulars of any other observations of importance which were recorded.

The land upon which the effluent from the contact beds flows is a stiff soil overlying the London clay, the soil varying from 9 to 12 inches in thickness.

The solids from the sewage are now kept from covering the surface of the farm, allowing the soil to aerate, and the appearance of the farm is very much improved, as also the effluent from it.

(21) What inferences have been drawn from the experiment?

The single contact (coarse bed) is a most valuable assistance to broad irrigation, and enables an area of land to cleanse double the quantity of sewage that it would do without the contact beds.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

Our experience is only with one contact (coarse bed), the effluent still passing over the land in broad irrigation as it did before the contact beds were made.

(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

(*a*) Our cost for the beds has been 2*s*. 6*d*. per head for construction.

(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

(*b*) The cost of working the contact beds, including the extra pumping, will be about 1½*d*. per head per annum.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no Septic" action is produced.

T. Walker, Borough Engineer.
Signature of Officer under whose direction the experiment was conducted.

January 25th, 1901.

Form D.

PERMANENT WORKS FOR THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (SINGLE CONTACT).

Appendix 9C.

Name of authority - - - - - - -	The Hunslet Rural District Council.
Population of part of district referred to - . - -	Estimated at 2,000.
Water supply per head of the population - - -	8 gallons per day.
Estimated or measured dry weather flow of sewage -	
Is any trade refuse taken into the sewers? - - - If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No.
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the works are conducted - - -	Dr. Buck, M.O.H., Rothwell, Leeds.
Name and qualification of chemist who has made the analyses.	None made.
(1) What is the capacity in gallons of the subsidence tanks?	20,310 gallons.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	225 cubic ft. sludge weekly. Removed fortnightly.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(*b*) What was the depth of those beds? - - -	5 feet.
(*c*) What were the nature and size of the filtering material?	Bottom, 1 ft. 6 in. - - 2½ in. broken stones. Middle, 2 ft. 0 in. - - Broken clinkers. Top, 1 ft. 6 in. - - Coke breeze.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Only one class of beds.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(7) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Filled in, 2 hours; standing full, 2 hours; emptying and resting, 4 hours.
(10) State by what method the settled sewage was distributed on the beds.	Channel and pipes from settling tanks. Wooden spouts across centre of contact beds.

Appendix 9C

(11) What was the average quantity of sewage in gallons dealt with daily?	
(12) Was the quantity of sewage dealt with increased in time of storm?	Yes, very much.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper, or allowed to clear by standing before being analysed.	None made.
(14) Give (*a*) the average of the analyses of the final effluent from the beds.	
(*b*) The best analysis of the final effluent, and date when sample was taken, and	
(*c*) The worst analysis of the final effluent, and date when sample was taken.	
(*d*) The average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.	
(*e*) The average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(15) Give a typical analysis of the crude sewage to which the experiment relates.	
(16) Between what dates was the experiment conducted?	Been working 4 or 5 years.
If there were any periods of rest, state their duration.	
(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the works? - - -	No.
(19) Is the experiment still proceeding?	
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	West Riding Rivers Board Inspector has frequently expressed his satisfaction with the effluent.
(21) What inferences have been drawn from the experiment?	That the system, if properly worked, is very efficient in dealing with domestic sewage, but neglect in management would soon ruin the beds and render them worthless.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) What would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers?	Ten shillings per head.
(*b*) What would be the estimated annual cost per head of purifying the sewage of this system—excluding the annual repayment of any loan?	Sixpence.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

JOSEPH BUCK.

Signature of Officer under whose direction the experiment was conducted.

Form D.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS (DOUBLE CONTACT.)

Name of authority - - - - - - - - -	Keighley Corporation.
Population of district - - - - - - -	About 41,000.
Water supply per head of the population - - - -	About 32 gallons per day for domestic and trade purposes.
Estimated or measured dry weather flow of sewage- -	115,000 gallons per hour during daytime, or about $1\frac{3}{4}$ million gallons per day.
Is any trade refuse taken into the sewers? - - - -	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Woolcombers' suds, tanneries, yarn washing, magma or grease, dyewater, about 20 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted.	Borough Engineer.
Name and qualification of chemist who has made the analyses.	Rimmington & Son, Chemists, Bradford; Richardson, City Analyst, Bradford.

(1) What is the capacity in gallons of the subsidence tanks?	About 9,000 gallons. *Note.*—The experimental tanks are on a small scale.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	During the six months that the experiments have been tried there has been practically no accumulation of sludge.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	920 gallons at present.
(*b*) What was the depth of these beds? - - -	3 ft. 3 in. of coke.
(*c*) What was the size of the filtering material? -	Varying from 2 in. to $\frac{3}{4}$ in.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No measurements have been taken.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	*See* 5.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	920 gallons at present.
(*b*) What was the depth of these beds? - - -	3 ft. 6 in.
(*c*) What was the size of the filtering material? -	1 in. to $\frac{1}{4}$ in.
(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	No measurements have been taken.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	*See* 8.
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Three fillings per 24 hours. (*a*) 5 a.m., 1 p.m., and 9 p.m., or 8 hours. (*b*) 8 a.m., 5 p.m., and 1 a.m., or 3 hours full. (*c*) 5 minutes. (*e*) 5 hours empty or aerating.
(10) State by what method the settled sewage was distributed on the beds.	Through a 3 in. pipe into a wooden carrier 9 in wide and 6 in. deep, with grooves at sides.
(11) What was the average quantity of sewage in gallons dealt with daily?	Three times filling. 920 gallons × 3 = 2,760 gallons per day.
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.

Appendix 9C.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

Samples have been sent to F. Rimmington & Son, Chemists, Bradford, and F. W. Richardson, City Analyst, Bradford, and copies of reports are enclosed.

Analytical Laboratory, 9, Bridge Street, Bradford, 17th August 1900.

Certificate of Analysis of two samples of Sewage Water received from W. H. Hopkinson, Esq., A.M.I.C.E., Borough Engineer, Keighley.

The results are stated in grains per gallon.

	Crude Sewage.	Effluent.
Suspended matter - - - -	4·76	1·27
Total solid matter - - - -	27·75	30·45
Organic and volatile matter -	9·21	5·91
Saline matter - - - - -	18·54	24·54
Chlorine - - - - - -	3·08	3·22
Free ammonia - - - - -	1·395	0·2247
Albuminoid ammonia - - -	0·196	0·0448
Oxygen absorbed in three hours -	1·432	0·316

(signed) *F. M. Rimmington & Son.*

"Crude Sewage" taken out of carrier.

"Effluent" after passing detritus tank, sedimentation tank and 1st and 2nd contact beds.

City Analyst's Office, Bradford, 23rd August 1900.

Analytical Report upon two samples of Sewage from W. H. Hopkinson, Esq., Borough Engineer, Keighley. received 21st August 1900.

Grains per Gallon.

	Crude Sewage.	Effluent.
Total sediment - - - -	10·0	trace
In solution:		
Total solids - - - - - -	30·0	·46
Alkalinity equal to sulphuric acid	12·3	7·85
Oxygen absorbed in four hours -	·875	·150
Free ammonia - - - - -	1·05	·140
Albuminoid ammonia - - -	·455	·155

Percentage Purification effected on—

(1) The absorbed oxygen - - - -	82·6
(2) The albuminoid ammonia - - -	66·0
Average - - - -	74·3

The effluent shows a high degree of purification.

(Signed) *F. W. Richardson.*

"Crude Sewage" taken out of carrier.

"Effluent" after passing detritus tank, sedimentation tank and 1st and 2nd contact beds.

Analytical Laboratory, 9, Bridge Street, Bradford, 28th August 1900.

Certificate of Analysis of two samples of Sewage Water received from W. H. Hopkinson, Esq., A.M.I.C.E., Borough Engineer, Keighley.

The results are stated in Grains per Gallon.

	No. 1. 24 Aug.	No. 2. 25 Aug.
Suspended matter - - - -	23·15	0·49
Total solid matter - - - -	52·21	44·05

Oxygen absorbed in three hours -	3·708	1·524

(Signed) *F. M. Rimmington & Son.*

No. 1 crude sewage taken out of carrier.

No. 2 effluent from No. 2 intermittent filtration bed on contract drawing and 24 hours after crude sewage was put into the surface of the bed.

Appendix 9C

Analytical Laboratory, 9, Bridge Street. Bradford, 8th September 1900.

Certificate of Analysis of two samples of Sewage Water received from W. H. Hopkinson, Esq., A.M.I.C.E., Borough Engineer, Keighley.

The results are stated in Grains per Gallon.

	No. 1.	No. 2.
Suspended matter - - -	10·36	1·61
Total solid matter - - -	39·55	28·43
Organic and volatile matter -	17·50	9·89
Saline matter - - - -	22·05	19·54
Chlorine - - - - -	3·37	2·52
Free ammonia - - - -	1·477	0·616
Albuminoid ammonia - - -	0·539	0·2142
Oxygen absorbed in three hours -	2·013	0·7364

(Signed) *F. M. Rimmington & Son.*

No. 1 is a sample of crude sewage made up from quantities taken every hour.

No. 2 is a sample of effluent made up from quantities taken every hour from No. 15 intermittent filtration bed on contract drawings.

Analytical Laboratory, 9, Bridge Street, Bradford, 3rd October 1900.

Certificate of Analysis of two samples of Sewage Water, received from W. H. Hopkinson, Esq., A.M.I.C.E., Borough Engineer, Keighley.

The results are stated in Grains per Gallon.

	No. 1.	No. 2.
Suspended matter - - -	0·15	4·03
Total solid matter - - -	27·65	27·27
Organic and volatile matter -	11·94	5·79
Saline matter - - - -	15·71	21·48
Chlorine - - - - -	5·95	4·34
Free ammonia - - - -	3·178	1·05
Albuminoid ammonia - - -	0·287	0·182
Oxygen absorbed in three hours -	4·281	0·957

(Signed) *F. M. Rimmington & Son.*

No. 1 is crude sewage with a quantity of dye-water.

No. 2 is effluent after passing detritus tank, sedimentation tank and 1st and 2nd contact beds.

Analytical Laboratory, 9, Bridge Street, Bradford, 6th December 1900.

Certificate of Analysis of two samples of Sewage Water, labelled No. 1 and No. 2, received from W. H. Hopkinson, Esq., A.M.I.C.E., Borough Engineer, Keighley.

The results are stated in Grains per Gallon.

	No. 1.	No. 2.
Suspended matter - - -	12·35	nil
Total solid matter - - -	47·86	33·31
Organic and volatile matter -	26·24	8·58
Saline matter - - - -	21·62	24·73
Chlorine - - - - -	3·78	3·64
Free ammonia - - - -	1·288	0·217
Albuminoid ammonia - - -	0·546	0·091
Oxygen absorbed in three hours -	3·815	0·785

(Signed) *F. M. Rimmington & Son.*

No. 1 is crude sewage taken from carrier.

No. 2 is effluent after passing detritus tank, sedimentation tank and 1st and 2nd contact beds, but allowing five minutes to discharge from 1st and 2nd contact beds.

(*b*) The best analysis of the final effluent and date when sample was taken, and	*See* 14.
(*c*) The worst analysis of the final effluent and date when sample was taken.	*See* 14.
(*d*) The average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.	*See* 14.
(*e*) The average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	*See* 14. Samples can be examined. There are final samples that do not smell.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	*See* Analyses No. 1, 2, 5, and 6.
(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	Since August of 1900.

Appendix 9C.

(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None taken.
(18) Was any nuisance caused by the experimental works?	No. If a sample of the bed be taken out, there is only an *earthy* smell.
(19) Is the experiment still proceeding? - - - -	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes, with pleasure.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	That the effluent from the experimental tanks is good enough to go into the river without further treatment, and the cost of maintenance would be considerably less.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	It is considered practicable.
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	£26,000.
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Estimated at £500.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic action is produced.

W. H. Hopkinson, A.M.Inst.C.E., Borough Engineer.
Signature of Officer under whose directio
the experiment was conducted.

Form D.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS.

Northern Outfall—Coke beds dealing with rapidly sedimented crude sewage.

Name of authority - - - - - - -	London County Council.
Population of district - - - - - - - (Sewage derived from London north of Thames.)	3,251,974 (1896).
Water supply per head of the population - - -	34·8 gallons per day (1900).
Estimated or measured dry weather flow of sewage -	123,000,000 gallons per day (1900).
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Trade refuse from districts drained is taken into sewers. Quantity not known.
Is the storm, soil or surface weather, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted -	Professor Clowes, D.Sc.
Name and qualification of chemist who has made the analyses.	Mr. E. B. Pike.

(1) What is the capacity in gallons of the subsidence tanks?	1,000 gallons. Filled to within 6 inches of the top. The capacity is 950 gallons.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	About 9 gallons of sludge containing 89·5 per cent. of moisture, collected in each of the two subsidence tanks. The sludge was removed only once and for experimental purposes. The tanks had then been in use for 13 weeks.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent. In these experiments two subsidence tanks were used and filled up each time simultaneously with similar quality sewage. The settled sewage from each tank was led into a single contact bed, consisting in one case of coarse coke fragments and in the other of fine coke fragments.
(4) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	The capacity of the coarse bed was 41·7 per cent. of the tank capacity without the coke. This bed had been in use previously as a "secondary" bed.
(b) What was the depth of these beds?	6 feet.
(c) What were the nature and size of the filtering material?	Fragments of sifted coke of such a size as would pass a 2-inch and would be rejected by a ½-inch mesh.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not. Each of these tests was made after the bed had been resting about 9 hours.	see below

1900.	Capacity.
20 November - -	38·5 per cent. of capacity of tank without coke.
27 " - - -	38·8 "
4 December - - -	38·5 "
11 " - - -	37·8 "
18 " - - -	36·1 "
1901.	
1 January - - -	35·3 "
15 " - - -	34·7 "
23 " - - -	34·7 "
30 " - - -	35·4 "
5 February - - -	32·7 "
12 March - - -	32·0 "
4 June - - - -	32·2 "
2 July - - - -	34·0 "
30 " - - - -	33·3 "

(6) What was the water-holding capacity of the coarse beds at end of experiment?	30 July, 1901. 33·3 per cent.
If the measurement was made after resting, please give the duration of the resting.	After 9 hours resting.
(7) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	The capacity of the fine bed was 40·3 per cent. of the capacity of the tank without the coke. This bed had been in use previously as a "secondary" bed.
(b) What was the depth of these beds? - -	Six feet.
(c) What were the nature and size of the filtering material?	Sifted coke fragments of such a size as would pass a ½-inch mesh and would be rejected by a $\frac{1}{16}$-inch mesh.

Appendix 9C.

(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

All these capacity tests were made after the bed had been resting about 9 hours.

1900.	Capacity.
20 November - -	38·5 per cent. of capacity of empty tank without coke.
27 " - - -	38·8 "
4 December - - -	37·5 "
11 " - - -	37·8 "
18 " - - -	35·4 "
1901.	
1 January - - -	33·3 "
15 " - - -	32·6 "
23 " - - -	31·2 "
30 " - - -	30·6 "
5 February - - -	29·2 "
12 March - - -	26·7 "
4 June - - -	25·0 "
18 " - - -	22·9 "
2 July - - -	25·0 ,
30 " - - -	25·3 "

(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

25·3 per cent. (30th July, 1901) after resting 9 hours.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

One or two fillings per day.

(10) State by what method the settled sewage was distributed on the beds.

2-foot fall on to perforated boards 2 feet above the surface of the bed.

(11) What was the average quantity of sewage in gallons dealt with daily?

One filling 200 gallons } about.
Two fillings 400 " }

(12) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Average samples analysed daily.

Samples filtered except that used for estimating the total putrescible matter present.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

Averages of estimations made during the period 7th Nov., 1900-6th Aug., 1901:—

	Coarse bed.	Fine bed.
Solids in suspension - - -	10·	3·2
Solids in solution - - -	93·3	96·3
Oxygen absorbed from permanganate in four hours at 80° F.:		
By the total putrescible matter.	5·100	3·358
By the dissolved putrescible matter.	3·320	2·604
Nitrous nitrogen - - -	0·036	0·05674
Nitric nitrogen - - -	0·752	1·2931

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

	Coarse bed. 27 July, 1901.	Fine bed. 27 July, 1901.
(*b*) Suspended solids - -	10·	4·
Oxygen absorbed from permanganate in four hours at 80° F.:		
By total putrescible matter.	3·724	1·9610
By dissolved putrescible matter.	1·372	0·980
Nitrous nitrogen - -	nil	0·040
Nitric nitrogen - -	1·1245	1·5395
	28 June, 1901.	18 Jan., 1901.
(*c*) Suspended solids - -	44·	2·
Oxygen absorbed from permanganate in four hours at 80° F.:		
By total putrescible matter.	12·800	4·000
By dissolved putrescible matter.	7·600	3·800
Nitrous nitrogen - -	0·090	0·050
Nitric nitrogen - -	5·4079	1·0663

Appendix 9C.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

17·7 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Coarse bed.	Fine bed.
10·0	3·2

The effluents did not putresce in the laboratory.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

Average for the period 7th Nov., 1900–6th Aug., 1901.

	Sewage supplied to settling tank worked in connection with the	
	Coarse bed.	Fine bed.
Suspended solids - - - -	66·5	67·0
Oxygen absorbed from permanganate in four hours at 80° F.:		
By the total putrescible matter.	12·933	12·829
By the dissolved putrescible matter.	6·882	6·648
Nitrous nitrogen - - -	0·0115	0·0106
Nitric nitrogen - - -	0·0412	0·0326

(16) Between what dates was the experiment conducted? If there were any periods of rest, state their duration

7th Nov., 1900—6th Aug., 1901.

Series including tank and fine bed:—	Series including tank and coarse bed:—
12 days through frost.	10 days through frost.
36 single days at intervals.	15 single days at intervals.
Fine beds only:—	Coarse bed only:—
2 single days.	1 day.

Both settling tanks and both beds.
Every Sunday and
3 days at Christmas, 1900.
5 „ „ Easter, 1901.
3 „ „ Whitsuntide, 1901.
2 „ „ August Bank Holiday, 1901.

(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

None made.

(18) Was any nuisance caused by the experimental works?

No.

(19) Is the experiment still proceeding?

No.

If so, may the Commission inspect the works, should they deem it desirable to do so?

(20) Give particulars of any other observations of importance which were recorded.

(21) What inferences have been drawn from the experiment?

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

This system appears perfectly practicable and a non-putrescible effluent of satisfactory character would be obtained by its adoption.

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

A somewhat heavy expenditure would be incurred by pumping the effluent into the river during high water.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

FRANK CLOWES.

Signature of Officer under whose direction the experiment was conducted.
Chief Chemist to the London County Council.

Appendix 9C. Form D.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS.

Name of authority - - - - - - - -	Manchester.
Population of district - - - - - - -	516,000.
Water supply per head of the population - - -	
Estimated or measured dry weather flow of sewage -	21,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Mostly enter the sewers.
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	
Officer under whom the experiment has been conducted.	Gilbert J. Fowler, M.Sc., F.I.
Name and qualification of chemist who has made the analyses.	
(1) What is the capacity in gallons of the subsidence tanks?	
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(4) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	
(b) What was the depth of this bed?	3 feet.
(c) What was the nature and size of the filtering material?	Screened clinker. Rough material round the drain-pipes. Material uniform throughout the bed. Passed 3-inch mesh and rejected by 1-inch mesh.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse bed, stating in each case whether the measurement was made after resting or not.	See Bed A table below.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(b) What was the depth of this bed? - - -	Three feet.
(c) What was the nature and size of the filtering material?	Screened clinker. Rough material round the drain-pipes. Material uniform throughout the bed. Passed 1 inch mesh, rejected by ¼ inch mesh.
(8) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	See Bed B table below.
(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	

Bed A.

Date.	Capacity in Gallons.	Remarks.
12th Sept. 1898 -	5,688	
27th Oct. „ -	4,800	4¾ hours rest.
15th Nov. „ -	4,530	3 hours rest.

Bed B.

Date.	Capacity in Gallons.	Remarks.
9th Sept. - -	5,688	Material quite dry.
10 „ - -	5,004	2½ hours rest.
16th Nov. - -	4,530	3 hours rest. Drainage pipes full.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

Date. 1898	No. of fillings.	Cycle.
September 21st	1	(*a*) $\frac{3}{4}$ hour, (*b*) 2 hours, (*c*) $\frac{3}{4}$ hour, (*e*) remainder of time.
Sept. 21 to Oct. 26	2	Primary bed filled at 8 a.m. and 2 p.m. Working cycle as above.
Oct. 26 to Nov. 16	3	(*a*) $\frac{3}{4}$ hour, (*b*) 1 hour, (*c*) $\frac{3}{4}$ hour, (*e*) 4 hours. (*a*) $\frac{3}{4}$ hour, (*b*) 2 hours, (*c*) $\frac{3}{4}$ hour, (*e*) $2\frac{1}{2}$ hours. (*a*) $\frac{3}{4}$ hour, (*b*) 2 hours, (*c*) hour, (*e*) 8 hours.

(10) State by what method the settled sewage was distributed on the beds.

By means of wooden shoots perforated at the bottom of the sides.

(11) What was the average quantity of sewage in gallons dealt with daily?

9,000 (allowing for Sunday's rest).

(12) Was the quantity of sewage dealt with increased in time of storm. If so, state to what extent, and how the results were affected by such increase.

No.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(14) Give (*a*) the average of the analyses of the final effluent from the beds;

The following numbers are the average of daily analyses for the different periods stated, of the effluent from the Secondary Bed (B):—

Date.	Four Hours Oxygen Absorption.	Incubator Test. 3 mins. Oxygen Absorption. Before.	Incubator Test. 3 mins. Oxygen Absorption. After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
Sept. 14th-21st, 1898 - - - (1 filling per day).	2·47	1·44	2·03	43-6	1·[illegible]6	·14	·059	nil.	15·4
Sept. 21st-Oct. 26th, 1898 - - (2 fillings per day).	1·63	·90	·93	$27\frac{1}{2}$-68	1·10	·117	·033	·333	14·6
Oct. 26th-Nov. 16th, 1898 - - (3 fillings per day).	1·47	·70	·68	$10\frac{1}{2}$-52	0·77	·096	·016	·368	14·1

(*b*) the best analysis of the final effluent and date when sample was taken; and

(*c*) the worst analysis of the final effluent and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

(15) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of *Settled Sewage*, for the quarter ending December 29th, 1898:—

4 hours Oxygen Absorption - - -	7·21
3 minutes Oxygen Absorption - -	3·86
Ammoniacal Nitrogen - - - - -	2·04
Albuminoid Nitrogen - - - - -	·33
Chlorine - - - - - - - -	16·0

(16) Between what dates was the experiment conducted?

September 14th-November 16th, 1898.

If there were any periods of rest, state their duration.

The beds rested on Sundays; no other periods of rest.

(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

(18) Was any nuisance caused by the experimental works?

No.

(19) Is the experiment still proceeding? - - - -

No.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Appendix 9C.

(20) Give particulars of any other observations of importance which were recorded.	The following substances have been definitely recognised in the sewage which has at various times passed on filters, viz. :— Iron pickling refuse. Dye refuse. Carbolic acid. Sulpho-cyanates. The Iron Pickling Refuse (originally ferrous chloride) is completely oxidised in passing through the filters, some hydrated oxide of iron remaining in the filters. Dye Refuse—The colour is to a large extent, though not completely, discharged. Carbolic Acid—This appears to be oxidised in the filters. In no case has the presence of manufacturing waste shewn a marked tendency to render the purification less effective.
(21) What inferences have been drawn from the experiment?	Apparently it is not certain that non-putrefactive filtrate can invariably be obtained by treatment of fresh sewage by double contact, though experiences point out that the results would have improved on further working.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state (*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers; (*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

Gilbert J. Fowler,

Signature of Officer under whose direction the experiment was conducted.

Form D.

Appendix 9C

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS. (SINGLE CONTACT.)

Name of authority - - - - - - - -	Oldham Corporation.
Population of district - - - - - - -	155,865.
Water supply per head of the population - - -	$22\frac{1}{2}$ gallons per day.
Estimated or measured dry weather flow of sewage -	4,000,000 gallons per day (estimated).
Is any trade refuse taken into the sewers? If so, state from what process it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes. Tripe-boiling refuse, brewing refuse, and foul water from lodges of cotton mills; the latter is the worst we have to deal with, but the total quantity of trade refuse is a negligeable quantity.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	$\frac{1}{4}$ inch, partially excluded.
Officer under whom the experiment has been conducted -	Dr. James B. Wilkinson, Medical Officer of Health.
Name and qualification of chemist who has made the analyses.	A. S. Wylie.
(1) What is the capacity in gallons of the subsidence tanks?	2,116,800 gallons, *i.e.*, 12 tanks each holding 176,400.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	Unable to state weekly quantity, as each tank was working on an average three months before it was cleaned out. At the end of that time the sludge stood in the tank to a depth of 2 ft. 4 in. About 10,500 cubic feet of wet sludge.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Cubic capacity estimated at 40 per cent.
(*b*) What was the depth of these beds? - - -	From 2ft. to 2 ft. 9 in.
(*c*) What were the nature and size of the filtering material?	All the filters were made of furnace clinkers, all pieces which passed through a $\frac{1}{4}$ in. screen were rejected. Material was not graded in filters.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No observations made.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Experiment still in progress.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No fine beds used in experiments
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Each bed is filled twice in 24 hours. (*a*) Filling occupied from $\frac{1}{2}$ to $\frac{3}{4}$ of an hour. (*b*) Standing full—two or three hours. (*c*) Emptying—about two hours. (*e*) Resting—interval between 1st and 2nd filling, two hours at least, sometimes more.

Appendix 9C.

(10) State by what method the settled sewage was distributed on the beds.	Distributed over the beds by means of wooden carriers.
(11) What was the average quantity of sewage in gallons dealt with daily?	484,000 gallons per acre.
(12) Was the quantity of sewage dealt with increased in time of storm?	No.
Is so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Samples are taken daily and are analysed the day following. Samples are *not* filtered through filter paper, and are *not* allowed to clear by standing. Each sample is well shaken before being analysed.
(14) Give (*a*) the average of the analyses of the final effluent from the beds;	0·9 of a grain per 100,000, absorbed in 4 hours test. 1·49 „ „ ammoniacal nitrogen. 0·19 „ „ albuminoid nitrogen. 0·4 „ „ nitric nitrogen. Chlorine varied of course according to strength of sewage, but there was no appreciable reduction on filtration.
(*b*) the best analysis of the final effluent and date when sample was taken; and	5th November 1900—·11 of a grain per 100,000, oxygen absorbed in 4 hours test.
(*c*) the worst analysis of the final effluent and date when sample was taken;	18th July 1900—2·05 grains per 100,000, oxygen absorbed in 4 hours test.
(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	No estimations of solids in suspension have been made.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Samples of the final effluent are regularly incubated, and are not putrescible on the whole. During very hot weather, owing to the tank effluent becoming septic, there are occasionally samples which become putrescent.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	4th July 1900. (see table below)

4th July 1900.

Oxygen absorbed in 4 hours test.	Ammoniacal nitrogen.	Albuminoid nitrogen.	Chlorine.
5·65	3·5	1·2	Not estimated.
	parts per 100,000.		

(16) Between what dates was the experiment conducted?	From the beginning of 1899, and the process is still going on.
If there were any periods of rest, state their duration.	Yes. Periods of rest are every Sunday, and also from 20 to 60 days in the year. Longest period about a fortnight at once.
(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	No observations made.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	17th December 1900. Owing to the "Beer Poisoning Epidemic" about 200 barrels of beer were turned into the sewer on one day, and the figures went up to the following numbers on that date. Oxygen absorbed in 4 hours test, grains per 100,000: Tank effluent, 13·2 grains per 100,000. Filters, from 1·73 to 4·3 grains per 100,000. and nitrification ceased for almost a week. After a long period of rest the filtrate is heavily charged with nitrates. One sample gave 8·6 grains per 100,000.
(21) What inferences have been drawn from the experiment?	That this method of treatment will satisfactorily purify the sewage of Oldham, provided a tank effluent can be obtained which does not become septic in warm weather. This can be obtained by sufficient sludge-pressing accommodation, so that the subsidence tanks can be cleaned out more frequently. The tanks are liable to become extremely foul in summer, with a very large quantity of solids in suspension. The change from a comparatively weak tank effluent in winter to a highly septic tank effluent in summer, has a bad effect on the purifying powers of the filter. In some cases only one filling per 24 hours has been dealt with. The inference from this is, that in summer a considerable quantity of solid organic material is treated in the filter beds, which in winter is deposited as sludge.

(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes. It it is intended to treat it by this method.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers ;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Cannot say at present.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;

Albuminoid nitrogen ;

Nitrous nitrogen ;

Nitric nitrogen ;

Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no septic" action is produced.

JAMES B. WILKINSON, M.D., C.M., D.P.H.,

the experiment was conducted.

Appendix 9C. Form D.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority - - - - - - - -	Corporation of Oswestry.
Population of district - - - - - - -	100,000.
Water supply per head of the population - - -	21 gallons per day.
Estimated or measured dry weather flow of sewage -	June and July, 1900, 387,000 gallons per day.
Is any trade refuse taken into the sewers? - - - If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes; Brewery, Tannery, and Fellmongers. Probably one-sixth.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted -	G. William Lacey, Borough Engineer and Surveyor.
Name and qualification of chemist who has made the analyses.	G. William Lacey, Borough Engineer and Surveyor.

(1) What is the capacity in gallons of the subsidence tanks?	56,000.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	About 200 cubic ft. per week removed at from 8 to 10 weeks intervals.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Difficult to say exactly on account of the absorption of the earthen banks and floors. Approximately for the 8 beds in use 240,000 gallons.
(*b*) What was the depth of these beds? - - -	4 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Cinders $\frac{3}{8}$ in. to $1\frac{1}{2}$ in.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Gaugings on a 24-hour diagram of the flow of sewage are taken almost daily, and special gaugings have been taken periodically to ascertain the capacity of the coarse beds. Taken under the ordinary working conditions of periodical rest.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	The capacity at the present time of the 8 beds in work is about 162,000 gallons. Loss 30 per cent. No. On ordinary working conditions.
(7) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds, when filled with the filtering material?	Not gauged. Approximately (8 beds) 168,000.
(*b*) What was the depth of these beds? - - -	4 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Cinders $\frac{3}{8}$ in. to 1 in.
(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	At the present time, so far as can be judged, the loss of capacity is exceedingly small.
(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	This varies with the rate of flow. It will average not quite 3 fillings per day. Sometimes of course more and sometimes less. If three fillings per day, each bed as follows: filling 1 hour, standing full 2 hours, emptying 1 hour, resting 4 hours. Every bed has one week's entire rest in nine.

(10) State by what method the settled sewage was distributed on the beds.	From a central automatic valve arrangement over wood troughs. Four distributing troughs to each bed.
(11) What was the average quantity of sewage in gallons dealt with daily?	440,000 (1900).
(12) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Yes, considerably. Quantities treated have ranged up to 783,000 gallons per day. Effluents during very heavy storms somewhat turbid. The beds have not been injuriously affected thereby.
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Various intervals. Nearly every month since works completed. Sometimes several times a week. The analyses are as a rule made the day following the taking the samples. Samples not filtered.

(14) Give (*a*) the average of the analyses of the final effluent from the beds.

	parts per 100,000.
Chlorine	10·4
Free ammonia	·557
Albuminoid ammonia	·183
Oxygen absorbed in 20 minutes	·41

This is the average of 55 analyses taken from July 1899 to January 1901. The average percentage of purification over the whole period being albuminoid ammonia 89·5, and oxygen absorbed 88·4.

(*b*) the best analyses of the final effluent and date when sample was taken, and

7th November, 1899.

	parts per 100,000.
Chlorine	6·95
Free ammonia	·36
Albuminoid ammonia	·078
Oxygen absorbed in 20 minutes.	·30

(*c*) the worst analyses of the final effluent and date when sample was taken.

11th October, 1900.

	parts per 100,000.
Chlorine	9·3
Free ammonia	·48
Albuminoid ammonia	·408
Oxygen absorbed in 20 minutes	·54

Note.—The above is the only basis on which the analyses have been made.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.	Not obtained.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Not obtained. Effluents have been kept for two years without signs of putrescence.

(15) Give a typical analysis of the crude sewage to which the experiment relates.

10th April, 1900.

	parts per 100,000.
Chlorine	10·00
Free ammonia	5·1
Albuminoid ammonia	1·92
Oxygen absorbed in 20 minutes	3·6

(16) Between what dates was the experiment conducted? If there were any periods of rest state their duration.	In July 1896 small experimental beds were constructed by the late Borough Engineer, and in November 1897 the permanent beds were commenced and finally completed in June 1899, and have been in constant operation ever since.

(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

Some records during February 1901.

Air.	Sewage.	Bed (midway).
Degrees.	Degrees.	Degrees.
40	42	40
42	44	44
42	46	41
34	42	38
30	41	34
32	43	34
33	42	38
35	42	36

Appendix 9C.

(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - -	The works now in operation and which have been for two years past are permanent, and not experimental.
If so, may the Commission inspect the works should they deem it desirable to do so?	Yes.
(20) Give particulars of any other observations of importance which were recorded.	
(21) What inferences have been drawn from the experiment?	It is clearly demonstrated here that the sewage can be efficiently treated on the bacterial system.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	This has been done.
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	The works have cost £2,000, which is equal to 4*s.* per head of population.
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Sixpence per head including sludge disposal.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

G. William Lacey, Borough Engineer and Surveyor.

Signature of Officer under whose direction the experiment was conducted.

Form D. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority - - - - - - - -	Slough Urban Council.
Population of district - - - - - - -	About 7,000.
Water supply per head of the population : - - -	22 gallons per day.
Estimated or measured dry weather flow of sewage -	180,000 gallons per day.
Is any trade refuse taken into the sewers? - - -	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Elliman's Embrocation Works (only small quantities of refuse received).
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted.	W. W. Cooper, surveyor, Slough.
Name and qualification of chemist who has made the analyses.	W. W. Fisher, county analyst, Oxford.

(1) What is the capacity in gallons of the storage tanks?	About 72,000 gallons.
(2) State what quantity of sludge was produced weekly in the storage tanks, and at what intervals the sludge was removed.	The tanks are used as storage tanks, and any sludge that accumulates is passed through the pumps to the farm.
(3) State whether the flow of sewage through the storage tanks was continuous or intermittent.	Continuous into; but only continuous through when the pumps are being worked.
(4) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	240 gallons.
(b) What was the depth of these beds? - - -	Two small beds, 3 ft. deep × 4 ft. × 4 ft.
(c) What were the nature and size of the filtering material?	Screened boiler ashes or clinker. 1 coarse bed, 1 fine bed.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	240 gallons per day. The 2 beds were filled twice a day for 6 days per week only as follows:— Time filling coarse bed - - - ½ an hour „ standing full - - - - - 2 hours „ emptying - - - - - ½ an hour „ empty - - - - - - 2 hours The effluent from coarse bed discharged on to fine bed, which was worked on the same system. The quantity of crude sewage treated per day was 240 gallons.
(6) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Not more than one-half the original capacity.
(7) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	240 gallons per day.
(b) What was the depth of these beds?	3 feet.
(c) What were the nature and size of the filtering material?	Screened boiler ashes or clinker.
(8) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	

Appendix 9C.

(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting. — Less than one half of original capacity.

(9) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (a) filling, (b) standing full, (c) emptying, and (e) resting. — See answer to query 5.

(10) State by what method the settled sewage was distributed on the beds. — Wooden troughs.

(11) What was the average quantity of sewage in gallons dealt with daily? — About 200 gallons.

(12) Was the quantity of sewage dealt with increased in time of storm? — No.

If so, state to what extent, and how the results were affected by such increase.

(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed. — Only one analysis.

Reference No. 2973.

To the Urban District Council, Slough.

Report on a sample of Effluent Water.

Received 18th July 1899,

From Mr. W. W. Cooper.

Effluent from Bacteria Bed.

Appearance :—Very slightly turbid.
Sediment :—Small.
Odour :—None. Sulphuretted hydrogen. 0.
Colour after filtering :—Nearly colourless.

The results of the analysis are stated in grains per gallon.

Total solid matter in suspension :—Not determined.

Mineral matter in suspension :—Not determined.

Organic and volatile matter :—Not determined.

	Grains.
Total dissolved solid matter - - -	65·8
Chlorine as chlorides - - - - - -	9·1
equals common salt - - - - - -	15·0
Ammonia free and saline - - -	1·37
Albuminoid ammonia - - - - -	0·058
Nitrogen as nitrates and nitrites - - -	3·15
equals nitric acid - - - - - -	0·1
Oxygen absorbed by organic matter in three hours - - - - - - - -	0·360

Remarks :—The effluent is nearly free from suspended matters, is without odour and nearly colourless, the proportion of organic matter estimated by albuminoid ammonia and oxygen absorbed is well below the standards for such discharges.

The large amount of nitrates shows an active healthy condition of the bacteria bed. The effluent is very satisfactory.

(Signed) ***W. W. Fisher***, F.I.C.,
Public Analyst for Oxford, Bucks, &c.

Oxford, 31st July 1899.

---

(14) Give (a) the average of the analyses of the final effluent from the beds.

(b) the best analysis of the final effluent and date when sample was taken, and

(c) the worst analysis of the final effluent and date when sample was taken.

(d) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

(15) Give a typical analysis of the crude sewage to which the experiment relates. — Not taken.

(16) Between what dates was the experiment conducted? If there were any periods of rest state their duration. — March 22nd, 1899 to March 14th, 1900. Beds actually worked 266 days

Appendix 9C.

(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(20) Give particulars of any other observations of importance which were recorded.	On the whole, good effluents were obtained.
(21) What inferences have been drawn from the experiment?	Screened boiler ashes are not a suitable material. The sewage causes it to disintegrate, and by so doing the coarse bed becomes more readily choked. That subsidence tanks are advisable.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Not estimated.
(a) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(b) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

W. W. Cooper, Surveyor.

Signature of Officer under whose direction the experiment was conducted

Appendix 9C.

Form D.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS AND CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority - - - - - - - -	Stanley Urban District, Co. Durham.
Population of district - - - - - - - -	(South Moor.) 4,560.
Water supply per head of the population - - -	Ten gallons per day.
Estimated or measured dry weather flow of sewage -	45,000 gallons per day.
Is any trade refuse taken into the sewers? - - -	No.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted -	T. Eustace Hill, M.B., B.Sc., F.I.C., Member of Society Public Analysts, County Medical Officer of Health.
Name and qualification of chemist who has made the analyses.	- - - ditto - - ditto.

(1) What is the capacity in gallons of the subsidence tanks?	24,360.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	About 8 to 9 cwt. per week. Once in 2 months sludge is removed.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent	Intermittent.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Notes as to this mislaid. No appreciable reduction in capacity up to date.
(*b*) What was the depth of these beds? - - -	Rough beds 4 feet 6 inches deep. Fine beds 3 feet deep.
(*c*) What were the nature and size of the filtering material?	Rough beds. Coke breeze and clinkers from 1½ to 3 inches. Fine beds. Coke breeze, screened by ⅜-inch screen.
(5) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No experiments made.
(6) What was the water-holding capacity of the coarse beds at end of experiment?	No experiments made.
If the measurement was made after resting, please give the duration of the resting.	
(7) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Not estimated.
(*b*) What was the depth of these beds? - - -	3 feet.
(*c*) What were the nature and size of the filtering material?	Coke breeze, screened by ⅜-inch screen
(8) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	Not taken.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	

Appendix 9C.

(9) State method of working of contact beds, *i.e.* number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	
) State by what method the settled sewage was distributed on the beds.	Conveyed by longitudinal channels, but not necessary. Fine beds, sewage run on and sinks in.
(11) What was the average quantity of sewage n gallons dealt with daily?	32,520 for 12 hours.
(12) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	
(13) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	From February 1899 to February 1901, 53 samples of fine tank effluent were analysed. The samples were not filtered before being analysed, as none of them contained any appreciable quantity of suspended matter.
(14) Give (*a*) the average of the analyses of the final effluent from the beds;	The average of 53 samples was as follows, in parts per 100,000.

		*
Free ammonia - - - -	2·897	1·549
Organic ammonia - - - -	0·141	0·072
Oxygen absorbed in three hours at 80° Fahr. - - - - - -	0·362	0·226
Chlorine as chlorides - - -	11·20	10·70
Total solid matter dried at 212° Fahr.	104·9	93·9
Nitrogen as nitrates - - -	0·950	1·076

* Prior to May 1899 bacterial action was not established in the tanks and consequently analyses prior to that time do not represent the purifying action of the bacteria. The figures marked * are the average of 47 analyses from May 1899 after bacterial action was set up.

(*b*) the best analysis of the final effluent and date when sample was taken; and

(*c*) the worst analysis of the final effluent and date when sample was taken;

Parts per 100,000.

	(*b*) Best sample 2 Mar. 1900.	(*c*) Worst sample 2 Mar. 1899.*
Ammonia - - - - -	0·045	12·50
Organic ammonia - -	0·015	0·85
Oxygen absorbed in three hours at 80° Fahr. - -	0·080	2·54
Chlorine as chlorides - -	3·40	16·30
Total solid matter dried in 212° Fahr. - - -	57·8	138·40
Nitrogen as nitrates - -	1·375	nil

* Bacterial action not established.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;	30·0 parts per 100,000 by weight.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Not appreciable and not determined. Effluents always clear and colourless after bacterial action was fully established in May 1899.
(15) Give a typical analysis of the crude sewage to which the experiment relates.	Average of 37 Samples.

Free ammonia - - - - - -	10·35
Organic ammonia - - - - -	1·691
Oxygen absorbed in three hours at 80° Fahr.	5·030
Chlorine as chlorides - - - -	13·4
Total solid matter dried at 212° Fahr. -	144·2
Nitrogen as nitrates - - - - -	nil

(16) Between what dates was the experiment conducted?	February 1899 and February 1901.
If there were any periods of rest, state their duration.	None.
(17) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None.
(18) Was any nuisance caused by the experimental works?	No.
(19) Is the experiment still proceeding? - - - -	Yes works still acting very satisfactorily.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.

Appendix 9C.

(20) Give particulars of any other observations of importance which were recorded.	1. Not affected by frost. 2. Night sewage and storm water can be dealt with. 3. Slight reduction in capacity of coarse tanks; none in fine tanks after two years. 4. Clinkers and coke breeze a good material for contact tanks; does not crumble. 5. No impairment of vital action of bacteria by keeping sewage in contact with material in coarse and fine contact tanks for 8 or 10 or even 12 hours. 6. Purifying action in coarse beds probably largely due to anaerobic organism. 7. Not less than four double contact tanks should be erected if the sewage is to be purified by that system.
(21) What inferences have been drawn from the experiment?	That a strong domestic sewage can be efficiently purified by double contact bacteria tanks, which can be erected at a moderate cost and maintained at a very small annual expense.
(22) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	About 5s. or less, but depends on district and cost of material.
(a) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers;	
(b) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

JOSEPH ROUTLEDGE,
Surveyer and Inspector.
Signature of Officer under whose direction the experiment was conducted.

16th March, 1901.

Form E.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (SINGLE CONTACT.)

Name of authority	Newbury (Borough).
Population of district	(about) 12,000.
Water supply per head of the population	18 to 20 gallons per day.
Estimated or measured dry weather flow of sewage	350,000 gallons per day, including subsoil water leakage into the sewers.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes, from four breweries; proportion is about 8 per cent. of flow of sewage exclusive of subsoil water.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Wholly excluded.
Officer under whom the experiment has been conducted	Borough Surveyor.
Name and qualification of chemist who has made the analyses.	James Brierley, Public Analyst, Southampton.

Note.—The experiments have been made on one class of bed only, no "roughing" or screening being necessary.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the beds when filled with the filtering material?	Capacity of beds = 200 yards cube. 16,000 gallons.
(*b*) What was the depth of these beds?	4 ft.
(*c*) What were the nature and size of the filtering material?	Bed I., clinker; Beds II. and III., gravel — Lowest 1 ft. 6 in.—$2\frac{1}{2}$ in. gauge. Middle 1 ft. 6 in.—$1\frac{1}{2}$ in. " Top 1 ft. 0 in.— $\frac{3}{4}$ in. "
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	At end of month from filling of Bed I. capacity dropped to 11,000 gallons. At end of 12 months capacity dropped to about 8,500 gallons. The capacity of the two gravel beds has decreased in 9 months from 16,000 gallons to about 9,000 gallons.
(3) What was the water-holding capacity of the beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Experiment still in progress. *See* answer to (2).
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	
(*c*) What was the nature and size of the filtering material?	
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(3) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Filled - 5 to 6 a.m. Standing full - 6 to 8 a.m. Emptied - 8 to 9 a.m. At rest - 9 to 11 a.m. Filled - 11 to 12 noon. Standing full - 12 to 2 p.m. Emptied - 2 to 3 p.m. At rest - 3 to 5 p.m. Filled - 5 to 6 p.m. Full - 6 to 8 p.m. Emptied - 8 to 9 p.m. At rest - 9 p.m. to 5 a.m.

Appendix 9C.

(7) State by what method the sewage was distributed on the beds.

By a level trough at both ends of each bed.

(8) What is the average quantity of sewage in gallons dealt with daily?

About 25,000 gallons per day on each bed (we have three).

(9) Was the quantity of sewage dealt with increased in time of storm?

Not appreciably.

If so, state to what extent, and how the results were affected by such increase.

- - -

(10) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper, or allowed to clear by standing before being analysed.

Only one set of analyses have been made, viz., of the clinker bed at end of 12 months' working, and of the gravel bed at end of 9 months' working.

(11) Give (*a*) the average of the analyses of the final effluent from the beds;

(*b*) the best analysis of the final effluent, and date when sample was taken; and

(*c*) the worst analysis of the final effluent, and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed;

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Analyses of two samples of effluent from Newbury, received 20th and 30th November, 1900:

Sample No. 1, from "clinkers," 19th November, 1900.

Physical characters:

Turbid, of deep reddish brown colour, black spot on white ground visible through 10 inches of effluent.

Chemical Analysis.

—	Parts per 100,000.	Grains per gallon.
Free ammonia - - -	3·8	2·66
Albuminoid ammonia - -	0·17	0·119
Nitrates - - - - -	Absent.	—
Chlorine as chloride - -	9·5	6·65
Equal sodium chloride -	15·65	10·955
Volatile solids - - -	24·0	16·8
Fixed solids - - -	42·0	29·4
Total solids - - - -	66·0	46·2

Oxygen absorbed in 15 minutes at 80° Fahr. 0·415 - 0·2905

Oxygen absorbed in 4 hours at 80° Fahr. 1·08 - - 0·765

Sample No. 2, from "gravel," 19th November, 1900.

Physical characters:

Turbid, deep yellowish red colour, black spot on white ground visible through 15 inches of effluent.

Chemical Analysis.

—	Parts per 100,000.	Grains per gallon.
Free ammonia - - -	4·3	3·01
Albuminoid ammonia - -	0·166	0·1162
Nitrogen as nitrates - -	0·05	0·035
Chlorine as chloride - -	8·0	5 6
Equal to sodium chloride -	13·18	9·22
Volatile solids - - -	25·0	17·5
Fixed solids - - -	44·0	30·8
Total solids - - - -	69·0	48·3

Oxygen absorbed in 15 minutes at 80° Fahr. 0·3751 0·2625

Oxygen absorbed in 4 hours at 80° Fahr. 0·9994 - 0·6995

Remarks.

Both samples have been thoroughly broken down, so far as their nitrogenous matters are concerned, and the nitrogen nearly all converted into free ammonia. Sample No. 2 is superior in clearness, colour, and oxidation to sample No. 1.

Both are well within the limits requred.

(12) Give a typical analysis of the crude sewage to which the experiment relates.

(13) Between what dates was the experiment conducted?

December, 1899, and present date.

If there were any periods of rest, state their duration.

Appendix 9C.

(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths	None made.
(15) Was any nuisance caused by the experimental works?	No.
(16) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Certainly.
(17) Give particulars of any other observations of importance which were recorded.	Our experiments have proved to us that *clean*, sifted shingly gravel is superior to clinker for contact beds. We are about to instal five extra beds of gravel, 5 ft. 6 in. deep, and hope, should we be favoured with a visit from your Commissioners, that these will be in working order for inspection. Not many analyses have been made, for the reason that the expense of this work has been considered prohibitive.
(18) What inferences have been drawn from the experiment?	*See* above.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	About 7*s*. to 10*s*. a head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	About 6*d*. per head per annum.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

S. J. L. Vincent.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C

Form E

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (SINGLE CONTACT.)

Name of authority	Urban District Council of Newton-in-Makerfield, Lancs.
Population of district	(Estimated) 16,800.
Water supply per head of the population	15 gallons per day.
Estimated or measured dry weather flow of sewage	(Measured) 141,400 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Engineering works in district discharge blow-off from boilers, and some wagon-grease and oil from lubricating gets into the sewers. No breweries, no tanneries, no chemical works. Say 1 per cent. trade refuse.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially excluded.
Officer under whom the experiment has been conducted.	Arthur Bowes, A.M.Inst.C.E., Surveyor to the Council.
Name and qualification of chemist who has made the analyses.	J. Campbell Brown, D.Sc. (County Analyst.)

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material? (*b*) What was the depth of these beds? (*c*) What was the nature and size of the filtering material? (2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not. (3) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	No coarse beds.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Not measured. Capacity before filling: 105,470 gallons at No. 1 works; 131,250 „ „ No. 2 „
(*b*) What was the depth of these beds?	Three feet.
(*c*) What were the nature and size of the filtering material?	Screened hard clinker, and cinders. Bottom 18 inches; clinkers between 1 inch and 2 inch. Top 18 inches; cinders between $\frac{1}{4}$ inch and $\frac{1}{2}$ inch. All fine dust removed.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	None.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Not measured.
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Usually 2 hours filling, always 2 hours full, 2 hours emptying, and 6 to 18 hours resting.
(7) State by what method the sewage was distributed on the beds.	Wooden troughs with V notches in sides.
(8) What was the average quantity of sewage in gallons dealt with daily?	50,223 gallons at one works (No. 1). 91,207 gallons at the other (No. 2).
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Increased to nearly three times normal.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	On two occasions only. *See* 11 and 12.

Appendix 9C.

(11) Give (*a*) the average of the analyses of the final effluent from the beds;

(*b*) the best analysis of the final effluent and date when sample was taken; and

10th July, 1900.

Total solids in solution - - -	74·8 per 100,000
„ „ in suspension - -	14·6 „
Ammonia - - - - - - -	3·47 „
Ammonia from organic matter - -	·42 „
Nitrogen as nitrates and nitrites -	·00 „
Combined chlorine - - - -	10·00 „
Oxygen absorbed in 3 minutes -	1·3 „
Oxygen absorbed in 4 hours - -	4·6 „

The percentage of solids removed mechanically from suspension is 90 per cent.

The percentage of improvement in ammoniacal matters is 80 per cent.

(*c*) the worst analysis of the final effluent and date when sample was taken;

(*c*) 22nd November 1900.

Total solids in solution - - -	71·40 per 100,000.
„ „ in suspension - -	18·00 „
Ammonia - - - - - -	2·37 „
Ammonia from organic matter -	5·95 „
Nitrogen as nitrates and nitrites -	·000 „
Combined chlorine - - -	8·200 „
Oxygen absorbed in 3 minutes -	·63 „
Oxygen absorbed in 4 hours - -	3·39 „

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed;

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

(12) Give a typical analysis of the crude sewage to which the experiment relates.

10th July 1900.

Total solids in solution - -	87·00 per 100,000
„ „ in suspension - -	153·000 „
Ammonia - - - - - -	4·28 „
Ammonia from organic matter -	2·06 „
Nitrogen as nitrates and nitrites -	·00 „
Combined chlorine - - -	14·50 „
Oxygen absorbed in 3 minutes -	4·28 „
Oxygen absorbed in 4 hours - -	21·80 „

(13) Between what dates was the experiment conducted? — 16th March 1900, to present time.

If there were any periods of rest, state their duration. — None.

(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths. — No observations taken.

(15) Was any nuisance caused by the experimental works? — None.

(16) Is the experiment still proceeding? - - - - — Yes.

If so, may the Commission inspect the works should they deem it desirable to do so? — Yes.

(17) Give particulars of any other observations of importance which were recorded.

(18) What inferences have been drawn from the experiment? — The inference that such a method of treating sewage is eminently suited to this district, but requires to include a preliminary settling or septic treatment, and most probably a secondary filtration in addition to the one referred to in these notes.

(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

ARTHUR BOWES, A.M. Inst. C.E.
Signature of officer under whose direction the experiment was conducted.

Appendix 9C. Form E.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS.

Name of authority	Eastry Rural District Council.
Population of district	1,000.
Water supply per head of the population	
Estimated or measured dry weather flow of sewage	24,000 gallons per day.
Is any trade refuse taken into the sewers?	Brewery waste; about 30 per cent.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Separate water supply not measured.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Drainage of back yards and roofs only admitted.
Officer under whom the experiment has been conducted	F. D. Anson, 15, Dean's Yard, Westminster, S.W.
Name and qualification of the chemist who has made the analyses	Sidney Harvey, F.I.C., Public Analyst, City and County of Canterbury.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Two, holding 4,000 gallons each.
(*b*) What was the depth of these beds?	3 feet 6 inches.
(*c*) What was the nature and size of the filtering material?	Coke broken to a 2-inch gauge.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No exact measurements were made of the liquid capacity of the beds, but it was found that after about 8 weeks' working, the capacity of the beds reached a constant quantity, from which they have not varied very much.
(3) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting	
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	
(*b*) What was the depth of these beds?	4 feet.
(*c*) What was the nature and size of the filtering material?	Second bed, coke broken to a ¾-inch gauge; third bed, a large cask filled with coke broken to a ¼-inch gauge.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	(*a*) See (18). (*b*) 2 hours. (*c*) 1 hour. (*e*) See (18). 8 hours for the complete cycle on average.
(7) State by what method the settled sewage was distributed on the beds.	Allowed to flow on to the beds from distributing channels.
(8) What was the average quantity of sewage in gallons dealt with daily?	8,000 gallons.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.

Appendix 9C.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.

Only three analyses were made :—
May 29th, 1899.
June 24th, 1899.
August 31st, 1899.

(11) Give (*a*) the average of the analyses of the final effluent from the beds.

AVERAGE OF THESE ANALYSES.

	No. 1 Crude Sewage.	No. 2 Effluent after 1st Treatment.	No. 3 Effluent after 2nd Treatment.	No. 4 Effluent after 3rd Treatment.
		Parts per 100,000	Parts per 100,000	Parts per 100,000
Appearance - - -	Dark Brown	—	—	—
Smell - - - - -	Very offensive	—	—	—
Suspended matter (organic)	106·5	10·71	8·55	2·14
Suspended matter (mineral)	37·1	3·24	2·28	1·96
Suspended matter (total)	143·6	18·95	10.83	4·10
Matter in solution	154·84	146·11	134·12	135·94

Ammonia - - - - - -	1·27
Albuminoid ammonia - - - -	·09
Oxygen absorbed in 4 hours- - -	1·00

(*c*) the worst analysis of the final effluent and date when sample was taken.

31st August, 1899.

Appearance - - - - - - -	Slight
Smell - - - - - - - -	—
Suspended matter, organic - - -	3·06
„ „ mineral - - -	3·54
„ „ total - - -	6·60
Matter in solution - - - -	156·60
Combined chlorine - - - -	21·77
Nitrogen as nitrites - - - -	2·61
Ammonia - - - - - -	1·77
Albuminoid ammonia - - - -	·12
Oxygen absorbed in 4 hours- - -	1·40

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Apparently not putrescible.

(12) Give a typical analysis of the crude sewage to which the experiment relates.

Two samples :—

	July 23rd, 1898.	24th May, 1899.
	Parts per 100,000.	Parts per 100,000.
Appearance - - - - -	Very turbid and floculent	Deep brown colour.
Smell - - - - - -	Very offensive.	Very offensive.
Reaction - - - - -	Acid.	
Suspended matter, organic -	25·09	262·4
„ „ mineral -	3·27	79·2
„ „ total -	28·36	341·6
Matter in solution - -	104·30	246·1
Including chlorine - -	9.30	12·8
Ammonia - - - - -	2·70	3·3
Albuminoid Ammonia - -	·90	3·3
Oxygen absorbed - -	8·80	19·7

Appendix 9C

(13) Between what dates was the experiment conducted?	March, 1899, present time.
If there were any periods of rest, state their duration.	
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(15) Was any nuisance caused by the experimental works?	No complaint has come to my knowledge.
(16) Is the experiment still proceeding?	The beds are still being worked regularly.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(17) Give particulars of any other observations of importance which were recorded.	
(18) What inferences have been drawn from the experiment?	The sewage was allowed to flow direct into the first bed from the sewer, and the time of filling them consequently varied considerably, often occupying six or seven hours, while at other times they were filled in little over an hour. The result of this was that septic action was set up in these beds and they became inefficient. That in this case it is necessary to have some sort of receiving tank by means of which the flow on to the bed may be regulated, and the quality of the sewage made more uniform. The Council are now applying for a loan to enable them to construct works to deal with the whole of the sewage, by first passing it through a scum tank and afterwards into contact beds. This tank will also be used as a collecting tank from which the effluent will be discharged periodically.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	£2 10s.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Part of attendant's wages and interest on capital and occasional renewal of filtering material.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

Signature of Officer under whose direction the experiment was conducted.

Form E.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Hampton Urban District Council.
Population of district	7,000 (4,600 at present connected to sewage system).
Water supply per head of the population	No exact information, but as the dry-weather flow of sewage is at the rate of 22½ gallons per head, it is no doubt somewhat approximate thereto.
Estimated or measured dry weather flow of sewage	107,500 gallons per day, which includes 4,000 gallons of flushing water.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No, with the exception of that arising from slaughter-houses.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Wholly excluded.
Officer under whom the experiment has been conducted.	John Kemp, Assoc.M.Inst.C.E., Surveyor.
Name and qualification of chemist who has made the analyses.	Charles E. Cassall, F.I.C., Public Analyst for Kensington, St. George's Hanover Square, Battersea, and the administrative counties of Kesteven and Holland, Lincolnshire.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	20,000 gallons each bed. (The beds are five in number.)
(*b*) What was the depth of these beds?	4 feet.
(*c*) What were the nature and size of the filtering material?	Furnace refuse rejected by a ¾-in. mesh sieve. Anything above this size was used. Some pieces as large as 12 in. diameter.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Two of the coarse beds were measured in October 1900, after one year and 10 months working, and were found to have retained their original liquid capacity. One of the coarse beds was again tested at the beginning of February 1901, after nearly two years and three months working, and still found to maintain its original liquid capacity.
(3) What was the water-holding capacity of the coarse beds at end of experiment?	As stated above.
If the measurement was made after resting, please give the duration of the resting.	Measurements taken in actual working. No rest given.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	This was not taken, but it was equal at least to that of the coarse beds.
(*b*) What was the depth of these beds?	4 feet.
(*c*) What were the nature and size of the filtering material?	Furnace refuse passed through a ¾-in. sieve, and rejected by a ¼ inch sieve.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	None have been made.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	See above.
( ) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Two beds are filled once in 24 hours. " " " twice " " One bed always resting. (*a*) ¾ to 1 hour, (*b*) 2 hours, (*c*) 1 hour, (*e*) not less than 2 hours but varies considerably, as quantity of sewage not yet equal to full working capacity of beds.
(7) State by what method the sewage was distributed on the beds.	In shallow wooden troughs for 2 beds, for the remaining 3 beds the sewage runs direct on to the beds without any special means of distribution.
(8) What was the average quantity of sewage in gallons dealt with daily?	This has been a growing quantity from the first connection made to the sewers on the 8th Dec. 1898, until now, when the quantity is 107,500 gallons.

Appendix 9C.

(9) Was the quantity of sewage dealt with increased in time of storm?	Very slightly.
If so, state to what extent, and how the results were affected by such increase.	Not affected in any way.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Only one analysis has been made, this was on the 10th October 1899.
(11) Give (*a*) the average of the analyses of the final effluent from the beds.	Appearance in porcelain vessel 1 in. deep - Clean and bright; colourless. Appearance in 1-ft. vessel - Clean and bright: slightly greenish yellow tint. Odour - - - - - None. Reaction - - - - - Neutral. Total solid matters - - - 106·4 parts per 100,000. Chlorine as chlorides - - 18·5 „ „ Nitrogen as nitrates - - 2·52 „ „ Oxygen absorbed from permanganate, 30 deg., 4 hours. 4·00 parts per 1,000,000. Saline ammonia - - - 0·968 „ „ Organic ammonia - - - 0·448 „ „ Appearance of solids on ignition. Marked blackening. Nitrates - - - - - Marked traces.
(*b*) the best analysis of the final effluent and date when sample was taken, and (*c*) the worst analysis of the final effluent and date when sample was taken	Only one taken.
(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed.	Mr. Cassall states that the "raw sewage contained a large quantity of suspended matter."
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Only one made, the analyst stating that the effluent was entirely free from suspended matter, and devoid of offensive odour. After passing through land the effluent contained 4·8 parts per 100,000 of suspended matter.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Appearance in porcelain vessel 1 in. deep. Opaque and thick; strong sewage colour. Appearance in 1-foot tube - Ditto. Ditto. Odours - - - - - Very offensive. Reaction - - - - Faintly alkaline. Total solid matters - - - 278·4 per 100,000. Chlorine as chlorides - - 89·0 „ „ Nitrogen as nitrates - - 0·0 „ „ Oxygen absorbed from permanganate, 30 deg. C., 4 hours. 129·4 „ 1,000,000. Saline ammonia - - - 79·32 „ „ Organic - - - - - 15·2 „ „ Appearance of solids on ignition. Intense blackening (inflammable residue). Nitrates - - - - - Absent.
(13) Between what dates was the experiment conducted?	From Dec. 8th, 1898, and is still going on.
If there were any periods of rest, state their duration.	Each coarse bed rests one week out of five.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths	None have been made.
(15) Was any nuisance caused by the experimental works?	No.
(16) Is the experiment still proceeding? - - -	Yes.
If so, may the Commission inspect the works should they deem it desirable to do so?	Yes.
(17) Give particulars of any other observations of importance which were recorded.	Two of the coarse beds have a top layer of very large-sized rough clinker, and it is remarkable that the tops of the beds have only been disturbed twice in 12 months for cleansing. It has also been observed that if the growth of vegetables, which commences on these two beds in the early spring, be left undisturbed until autumn, and then pulled and cleared away, the top and body of the beds are perfectly clean, the paper and all solid matter having disappeared. It is found that the final effluent from the final contact is an excellent water for the boilers, leaving practically no incrustation or corrosion on the boiler. None but this water is used for condensing, cooling, and feed purposes.

Appendix 9C.

(18) What inferences have been drawn from the experiment?	In the first place, it should be stated that the treatment of the whole of the sewage of Hampton on bacteriological lines has not been regarded purely as an experiment, the Council and its advisers having previously visited various experimental works, and come to the conclusion that it was quite possible to treat the whole of the sewage of the district bacteriologically, and really the results have exceeded our expectations, more particularly as regards the liquid capacity of the coarse beds, which is fully maintained after two years working. The installation is easily worked and managed at a small cost as compared with chemical treatment. There is no doubt whatever that the whole of the sewage of any town, and of a purely domestic character, where the separate system in its entirety is adopted, could be similarly treated. It may here be stated that the effluent is constantly being analysed by the Thames Conservancy, by whom it is termed "a good effluent."
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers,	Actual cost at Hampton = 7*s.* 4*d.*
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	Actual cost at Hampton, 5*d.*

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

JOHN KEMP

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form E.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Huddersfield Corporation.
Population of district	105,000.
Water supply per head of the population	Domestic purposes 14 gallons per day, trade purposes nine gallons per day.
Estimated or measured dry weather flow of sewage	Measured 7,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes, a large quantity, chiefly from the scouring, dyeing and finishing of wool, &c.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	29 per cent. of dry weather flow.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	Borough Engineer.
Name and qualification of chemist who has made the analyses.	Percy Coward.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	The initial capacity of the coarse bed was 19,000 gallons.
(*b*) What was the depth of these beds?	3 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Ordinary furnace clinker and coke. Half inch to about four inches.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	See table below.

Date.	Capacity.	Previous rest.
1898. August 9th	19,000	Initial capacity.
1899. March 3rd	9,000	2 hours.
" May 31st	7,300	2 "
" July 11th	6,100	2 "
" October 17th	5,600	2 "
1900. January 24th	4,800	2 "

(3) What was the water-holding capacity of the coarse beds at end of experiment?	4,800 gallons after resting.
If the measurement was made after resting, please give the duration of the resting.	Two hours.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	19,000 gallons (approx.).
(*b*) What was the depth of these beds?	3 ft. 3 in.
(*c*) What were the nature and size of the filtering material?	Top 9 in. clinker ¼-in. to ⅝-in., 1 ft. 11 in. clinker ¼-in. to 1½-in.; bottom 7 in. clinker large pieces.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	At the commencement of the experiment the contents of the coarse bed about filled the fine beds.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	At the finish less than a third of the fine bed was filled by the contents of the coarse bed.

Appendix 9C.

(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Filled twice a day,

—	Coarse.	Fine.
(*a*) - - - - -	2 hours.	2 hours.
(*b*) - - - - -	4 ,,	4 ,,
(*c*) - - - - -	2 ,,	3 ,,
(*e*) - - - - -	16 ,,	15 ,,

(7) State by what method the sewage was distributed on the beds.	Troughs.
(8) What was the average quantity of sewage in gallons dealt with daily?	16,390 gallons per day.
(9) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were effected by such increase.	No.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Samples were analysed daily. Neither filtered through paper nor allowed to clear by standing.

(11) Give (*a*) the average of the analyses of the final effluent from the beds.

Nitrous and nitric nitrogen - - -	·171	(15 weeks).
Ammoniacal nitrogen - - - -	·30	(76 weeks).
Albuminoid nitrogen - - - -	·108	,,
Oxygen absorbed in four hours at 80° F.	2·04	,,
,, ,, in three minutes -	·69	,,

(*b*) the best analysis of the final effluent and date when sample was taken, and

Sept. 30th 1899.	
Ammoniacal nitrogen - - - -	·035
Albuminoid nitrogen - - - - -	·020
Oxygen absorbed in four hours at 80° F. -	·77
,, ,, in three minutes - -	·23

(*c*) the worst analysis of the final effluent and date when sample was taken.

Sept. 14th 1898.	
Ammoniacal nitrogen - - - -	·55
Albuminoid nitrogen - - - - -	·215
Oxygen absorbed in four hours at 80° F. -	4·34
,, ,, in three minutes - -	1·81

(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to to the coarse bed.	Not estimated.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Traces, not estimated. The effluent when kept for seven days at 80° Fah. in a stoppered bottle (completely filled) frequently became putrescent.

(12) Give a typical analysis of the crude sewage to which the experiment relates.

Albuminoid nitrogen - - - - - - -	·608
Total organic nitrogen - - - - - -	1·23
Ammoniacal nitrogen - - - - - - -	1·24
Nitrous and nitric nitrogen - - - -	·02
Oxygen absorbed in four hours at 80° F.:	
Sample shaken - - - - - - -	9·71
,, settled - - - - - - -	7·69
,, filtered - - - - - - -	5·31
Chlorine - - - - - - - - -	14·1
Reaction. Slightly alkaline to litmus.	

Solids.

In suspension—	
Mineral - - - - - - - -	16·4
Volatile - - - - - - - -	18·2
Total	34·6
In solution—	
Mineral - - - - - - - -	59·7
Volatile - - - - - - - -	11·8
Total	71·5

Total Solids.

Mineral - - - - - - - - -	76·1
Volatile - - - - - - - - -	30·0
Total	106·1

(13) Between what dates was the experiment conducted?	August 1898 to February 1900.
If there were any periods of rest, state their duration.	Sundays. Also one week in January, 1899, and one week in September, 1899.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None made.
(15) Was any nuisance caused by the experimental works?	No.

Appendix 9C

(16) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	Discontinued.
(17) Give particulars of any other observations of importance which were recorded.	Samples of deposit were taken from different parts of the coarse beds at various times, and the proportion of organic to mineral matter contained in them determined. The results obtained are as follows :—

—	Dried at 212° F.	
	Mineral per cent.	Organic per cent.
Average sample of deposit from :—		
Near troughs from surface to 12 in. down the bed, taken after heavy rains in February 1899 - -	93·8	6·2
Near troughs (within 18 in.) from surface to 18 in. down the bed taken after dry weather, October 1899 - - - - - - -	73·5	26·5
Peeled off clinker from 6 in. to 30 in. down the bed, but not within 18 in. of troughs, October 1899 - - - - - - -	64·2	35·8
Peeled off the surface of the bed, but not within 18 in. of the troughs, October 1899 - -	44·1	55·9
Taken off clinker within 24 in. of the bottom, when the bed was being taken out, March 1900 -	63·7	36·3

(18) What inferences have been drawn from the experiment?	That it would be possible to purify by triple contact the crude sewage of Huddersfield. That the rapid deposition of irreducible matter in the coarse beds would necessitate their renewal being of so frequent occurrence as to render it a far too costly scheme to be adopted.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	No.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	£1 3*s*. 7*d*.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

J. G. L. Campbell, M.Inst.C.E.

Signature of Officer under whose direction the experiment was conducted.

Form E.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS.

Northern Outfall. Small experimental beds fed with unscreened and unsettled raw sewage.

Name of authority	London County Council.
Population of district: (Sewage derived from London north of Thames.)	3, 251,974 (1896).
Water supply per head of the population	34·8 gallons per day (1900).
Estimated or measured dry weather flow of sewage	123,000,000 gallons per day (1900).
Is any trade refuse taken into the sewers?	Trade refuse from districts drained is taken into the sewers.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Quantity not known.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	Professor Clowes, D.Sc.
Name and qualification of chemist who has made the analyses.	Mr. E. B. Pike.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?

Primary coarse bed A:—68·7 per cent.
Primary coarse bed B:—70·3 per cent. of tank capacity without coke. (Measurement made with the coke dry.)

(*b*) What was the depth of these beds?

9 ft. 9 in.

(*c*) What were the nature and size of the filtering material?

Coke passed through a 2-in. mesh and rejected by a ½-in. mesh.

(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Date.	Primary coarse bed **A.**	Primary coarse bed B.
1899, 20th Sep. (After 2½ months' work.)	41·9	33·3
1899, 27th Oct.	32·3	32·7
„ 6th Dec.	31·3	27·6
1900, 4th Jan.	26·8	24·7
„ 7th Feb.	21·8	22·2

(3) What was the water-holding capacity of the coarse beds at end of experiment.

Last measurements as above.

If the measurement was made after resting, please give the duration of the resting.

Measurement made after 17 hours resting empty.

(4) (*a*) What was the water-holding capacity at commencement of experiment of the secondary beds when filled with the filtering material?

Secondary coarse bed A:—61·7 per cent.
Secondary fine bed B:—53·1 per cent. (Measurement made with the coke dry.)

(*b*) What was the depth of these beds?

9 ft. 9 in.

(*c*) What were the nature and size of the filtering material?

Coke. Course bed A.—Passed through a 2-in. mesh and rejected by ½-in. mesh.
Fine bed B.—Passed through a ½-in. mesh and rejected by a $\frac{1}{16}$-in. mesh.

(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the secondary beds, stating in each case whether measurement was made after resting or not.

Date.	Secondary coarse bed A.	Secondary fine bed B.
1899, 20th Sept.	56·8	48·1
„ 27th Oct.	54·9	46·9
„ 6th Dec.	53·1	48·1
1900, 4th Jan.	50·6	47·0
„ 7th Feb.	50·6	44·4

(*b*) What was the water-holding capacity of secondary beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

Last measurements as above. Measurements were made after 17 hours resting empty.

Appendix 9C.

(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods, of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Once a day from 4th July, 1899, to 9th Dec., 1899 (both inclusive). Twice a day from 11th Dec., 1899, to 30th Dec., 1899. (*a*) 45 minutes. (*b*) 2 hours. (*c*) 1 hour. (*e*) 20 hours for one filling daily. 8 hours for two fillings daily.
(7) State by what method the sewage was distributed on the beds.	Splashed on a board laid on the surface of the bed.
(8) What was the average quantity of sewage in gallons dealt with daily?	*About* 290 gallons per filling in each series A and B.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Daily averages. Filtered except in the case of the estimations of oxygen absorbed by the total putrescible matter.

(11) Give (*a*) the average of the analyses of the final effluent from the beds

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken

	Secondary coarse bed A.	Secondary fine bed A.
Oxygen absorbed from permanganate in four hours at 80° F.	2·309	1·467
Nitrous nitrogen - -	0·1096	0·0584
Nitric nitrogen - -	1·3256	2·2659
	4 Sept., 1899:	26 July, 1899
(*b*) Oxygen absorbed in four hours at 80° F.	1·053	0·626
Nitric nitrogen - -	3·4714	1·7549
	16 Aug., 1899:	21 Dec., 1899:
(*c*) Oxygen absorbed in four hours at 80° F.	4·000	3·857
Nitric nitrogen - -	2·510	0·3647

(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed.	49 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Not estimated. Non-putrescible.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Oxygen absorbed in 4 hours at 80° F. - 6·163 Nitrous nitrogen - - - - - - 0·0057 Nitric „ - - - - - - 0·1331
(13) Between what dates was the experiment conducted?	4th July, 1899, to 19th May, 1900.
If there were any periods of rest, state their duration.	On Sundays, four consecutive days in August, 1899; five consecutive days at Christmas; and during 1900 on Jan. 4, 18; Feb. 3, 7, 19, 20; Mar. 15, 17; April 12, 13, 14, 16, 17, 28; May 7, 8.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	In Series A. the interior of the primary bed, 4 hours after emptying, was 50·5° F. (=the temperature of the sewage supplied to the bed); the air outside was standing at 42° F. The interior of the secondary bed, four hours after emptying, was 48° F. (or 2° higher than the liquid from the primary bed, with which it had been filled); the temperature of the air outside was 41° F.
(15) Was any nuisance caused by the experimental works?	No.
(16) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(17) Give particulars of any other observations of importance which were recorded.	

Appendix 9C.

(18) What inferences have been drawn from the experiment?	It was proved that the primary beds rapidly and continuously decreased in capacity when they were fed with unscreened and unsedimented raw sewage. The secondary beds, however, suffered no such diminution in capacity.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(a) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers?	
(b) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan?	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen

FRANK CLOWES,

Signature of officer under whose direction the experiment was conducted.

Chief Chemist to the London County Council.

Appendix 9C Form E.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS.

Southern Outfall The 13-foot Coke Bed dealing with crude and settled sewage.

Name of Authority :	London County Council.
Population of District : (Sewage derived from London, South of Thames)	1,678,104 (1896).
Water Supply per head of the population.	34·8 gallons per day (1900).
Estimated or measured dry weather flow of sewage.	About 90,000,000 gallons per day (1900).
Is any trade refuse taken into the sewers?	Trade refuse is taken into the sewers.
If so, state from what process it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Quantity is not known.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted?	Professor Clowes, D.Sc.
Name and qualification of Chemist who has made the analyses	Mr. J. W. H. Biggs.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	51 per cent. of the empty tank calculated when the coke was wet.
(*b*) What was the depth of these beds?	13 feet (similar results were obtained by 4 feet and 6 feet beds).
(*c*) What were the nature and size of the filtering material?	Coke, which passed through a 2-inch mesh, and which was rejected by a 1-inch mesh.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	1899. April 11 - - - - - 7,900 June 8 - - - - - 6,670 Oct. 10 - - - - - 5,530 1900. Jan. 12 6,000. Rested from Dec. 22, 1899. June 16 6,000. Rested from April 5 to May 2.
(3) What was the water-holding capacity of the coarse beds at end of experiment?	Oct. 8, 1900, 6290. (Calculated on the capacity of the lower 6 feet of the bed.
If the measurement was made after resting, please give the duration of the resting.	From July 28, 1900, to Oct. 8, 1900.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No fine beds were used.
(*b*) What was the depth of these beds?	
(*c*) What were the nature and size of the filtering material?	
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	The history of the fine bed may be divided into three periods (*a*, *b*, and *c*). (*a*) The bed received *crude* sewage between February 27 and October 10, and was filled generally twice a day. Its capacity diminished rapidly, as is shown by the following figures:—March 9, 1899, capacity 7,900 gallons. June 8, 1899, capacity 6,670 gallons. (*b*) The bed received very roughly sedimented sewage between October 10 and April 5, and was filled twice a day to December 22, and three times a day to April 5. The capacity on January 12, 1900, was 6,000 gallons. (*c*) The bed received settled sewage between May 2 and July 28, 1900, and was filled four times a day. Its capacity on June 16, 1900, was 6,000 gallons. In October 8 was 6,290 gallons (calculated).
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting?	

Appendix 9C.

(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Number of fillings varied between one and four per day of 24 hours:— (*a*) $\frac{1}{2}$ to $\frac{3}{4}$ hour. (*b*) 2 hours. (*c*) 1 hour. (*e*) Variable. With one or two fillings per day, the bed rested throughout the night. With three or four fillings, the bed was worked during the night, and therefore rested $4\frac{1}{4}$ to $4\frac{1}{2}$ hours, or $2\frac{1}{4}$ to $2\frac{1}{2}$ hours.
(7) State by what method the sewage was distributed on the beds.	Splashing on to perforated wooden trays.
(8) What was the average quantity of sewage in gallons dealt with daily?	7,000 to 25,000.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Daily. Filtered through filter paper except in the case of the estimations of total putrescible matter as measured by the oxygen absorbed from permanganate.
(11) Give (*a*) the average of the analyses of the final effluent from the beds.	Oxygen absorbed from permanganate in four hours at 80° F.: By the total putrescible matter - - - - 3·749 By the dissolved putrescible matter - - - 2·556 Nitrous nitrogen - - - - - - - - 0·038 Nitric nitrogen - - - - - - - - 0·158 Throughout the experiment the average purification effected as judged by the oxygen absorbed from permanganate in four hours at 80° F. by the dissolved matter was 52·1 per cent.
(*b*) the best analysis of the final effluent and date when sample was taken, and	July 4, 1899.
(*c*) the worst analysis of the final effluent and date when sample was taken.	December 22, 1899. Oxygen absorbed from permanganate in four hours at 80° F.: (*b*) (*c*) By the dissolved putrescible matter 0·732 4·906 Nitrous nitrogen - - - - - Trace None Nitric nitrogen - - - - - 0·114 Trace (*c*) In this case the corresponding sewage was exceptionally bad.
(*d*) the average of the estimations made of the solids in suspension in the crude sewage as it went on to the coarse bed.	40 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Too small in amount to be estimated. Not putrescible.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Suspended solids - - - - - - - 40 Dissolved solids - - - - - - - 110 Oxygen absorbed from permanganate in four hours at 80° F.:— By the total putrescible matter - - - 8·000 By the dissolved putrescible matter - - 5·500 Nitrous nitrogen - - - - - - - None Nitric nitrogen - - - - - - - None Albuminoid nitrogen - - - - - - 0·350
(13) Between what dates was the experiment conducted?	Feb. 27, 1899, and July 28, 1900. Bed was filled 657 times.
If there were any periods of rest, state their duration	Periods of rest:— 1899.—March 9. March 30 to April 3. May 20 to 23. June 10 to 18. July 8, 9, 13, 16, 22 to 24, 26 to 30. August 5 to 8, 17 to 20. September 8, 30. October 10 to 12, 14, 15, 17 to 22. October 24 to November 6. November 13. December 11, 22 to January 12, 1900 1900.—April 5 to May 2. (All dates inclusive.)
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	No observations made

Appendix 9C.

(15) Was any nuisance caused by the experimental works?	No.
(16) Is the experiment still proceeding? - - - -	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(17) Give particulars of any other observations of importance which were recorded.	
(18) What inferences have been drawn from the experiment?	That the crude sewage cannot be dealt with without being subjected to a preliminary settling process, as the beds receiving crude sewage choke up rapidly. That where the sewage has been well settled to get rid of the greater portion of suspended solids, a bed will continue to work well without appreciable loss of capacity.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Frank Clowes.

Signature of Officer under whose direction the experiment was conducted.

Chief Chemist to the London County Council.

Form E.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN CONTACT BEDS.

Northern Outfall.—Small experimental beds. Kentish Ragstone, as a neutralising material, was tried comparison with coke.

Name of authority	London County Council.
Population of district (Sewage derived from London North of Thames).	3,251,974 (1896).
Water supply per head of the population	34·8 gallons per day 1900).
Estimated or measured dry weather flow of sewage	123,000,000 gallons per day (1900).
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Trade refuse from districts drained was taken into the sewers. Quantity not known.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted.	Professor Clowes, D.Sc.
Name and qualification of Chemist who has made the analyses.	Mr. E. B. Pike.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	Ragstone bed, 40 per cent.; Coke bed, 50 per cent. of empty tanks without material measurements taken after one week's work.
(*b*) What was the depth of these beds?	5 feet.
(*c*) What were the nature and size of the filtering material?	One bed of Kentish Ragstone; one bed of Coke. Both materials were of such a size as to pass a 4-inch mesh and be rejected by a ½-inch mesh.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	Ragstone bed 36·6 per cent.; Coke bed 39·0 per cent., measured after 16 weeks' work. Raystone bed 34·8 per cent., Coke bed 33·6 per cent.; measured after 24 weeks' work. The beds had not rested, as the capacities were measured by the quantities of effluent which ran from the bed. The drainings were not included.
(3) What was the water-holding capacity of the coarse beds at end of experiment?	Not estimated.
If the measurement was made after resting, please give the duration of the resting.	The beds were at work for 5 weeks after the last capacity measurements, as shown above, were taken.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Not estimated.
(*b*) What was the depth of these beds?	5 feet.
(*c*) What were the nature and size of the filtering material?	Ragstone which passed through ½-inch mesh, and which was rejected by a $\frac{1}{16}$ inch mesh. Coke of the same size.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	Capacities not taken.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting	
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting	Beds were filled once a day from September 22, 1898, to January 9, 1899 (inclusive), and twice a day from January 11, 1899, to April 15, 1899, (*a*) about 10 minutes, (*b*) 2 hours, (*c*) ½ hour, (*e*) 9 or 18 hours (1 or 2 fillings).
(7) State by what method the sewage is distributed on the beds	The beds were 4 feet square, and the sewage fell from the pipe on to a board 1 foot square, which rested on the surface of the bed.
(8) What was the average quantity of sewage in gallons dealt with daily?	Ragstone beds, 240 gallons; Coke beds, 275 gallons.

Appendix 9C.

(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase	No.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed	Daily Averages.—Samples were filtered through filter paper.
(11) Give (*a*) the average of the analyses of the final effluent from the beds.	Oxygen absorbed from permanganate in 4 hours at 80° F.: (*a*) Ragstone bed, 2·761. Coke bed, 1·994.
(*b*) the best analysis of the final effluent and date when sample was taken, and	Ragstone Bed: (*b*) Jan. 16, 1899 - 1·429. Coke Bed: Oct. 5, 1898 - - 0·714.
(*c*) the worst analysis of the final effluent and date when sample was taken.	Ragstone Bed: (*c*) Dec. 1, 1898 - 4·000. Coke Bed: Dec. 7, 1898 - - 3·143
(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed.	Crude unsettled sewage was supplied to the beds. 49 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent Were these putrescible?	Not estimated. Not putrescible.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Oxygen absorbed from permanganate in 4 hours at 80° F.: Average throughout the experiment, 5·424.
(13) Between what dates was the experiment conducted?	September 22, 1898, and April 15, 1899.
If there were any periods of rest, state their duration.	Sundays, 4 days at Christmas, and 2 days occasionally for boiler cleaning.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(15) Was any nuisance caused by the experimental works?	
(16) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(17) Give particulars of any other observations of importance which were recorded.	
(18) What inferences have been drawn from the experiment?	It was inferred that no advantage resulted from using ragstone containing calcium carbonate—a neutralising substance—in place of coke; it had been surmised that the presence of calcium carbonate might promote bacterial action.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

FRANK CLOWES,

Signature of Officer under whose direction the experiment was conducted.

Chief Chemist to the London County Council.

Form E.

Appendix 9

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Maidstone.
Population of district	35,000 (estimated).
Water supply per head of the population	16½ gallons per day.
Estimated or measured dry weather flow of sewage	1,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes. Brewery, paper mill, tan-yard and slaughterhouse are the principal.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Storm water is excluded from the sewers in about half of our drainage area.
Officer under whom the experiment has been conducted	The Borough Surveyor.
Name and qualification of chemist who has made the analyses.	Dibdin and Thudichum.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering materal?	12,000 gallons.
(*b*) What was the depth of these beds?	3 ft. 4 in.
(*c*) What were the nature and size of the filtering material?	Furnace clinkers rejected by ⅜ in. mesh sieve.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	
(3) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	14,000 gallons.
(*b*) What was the depth of these beds?	4 ft. 4 in.
(*c*) What were the nature and size of the filtering material?	Furnace clinkers passed through ½ inch mesh sieve, and with firedust afterwards removed.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(6) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Once and twice per day. (*a*) 40 minutes. (*b*) 2 hours at first, afterwards 1½ and 1 hour. (*c*) 1½ hours. (*e*) 2 hours and 1 day in 7.
(7) State by what method the sewage was distributed on the beds.	At first by means of open distributing channels. These were afterwards removed, and the effluent appeared equally good.
(8) What was the average quantity of sewage in gallons dealt with daily?	12,000 at each filling.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Sewage with a large proportion of storm water has been dealt with on the beds, but the beds are filled by means of a pump, and consequently the quantity dealt with has been always the same.
(10) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper, or allowed to clear by standing before being analysed.	April and May 1899. By standing.

Appendix 9C.

(11) Give (*a*) the average of the analyses of the final effluent from the beds.

Cl., 8·7 parts per 100,000.
Ammoniacal nitrogen, 2·13 parts per 100,000.
Albuminoid nitrogen, 0·23 parts per 100,000.
Oxygen absorbed, 4 hours, 3·20 parts per 100,000.
Suspended matters, traces.

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

Chlorine.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Oxygen Absorbed.	Suspended matter.
8·7	0·72	0·165	3·20	Trace, April 6, 1899.
9·1	2·73	·220	3·84	Trace, May 8, 1899.

(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to coarse bed.

81·0 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Trace. No.

(12) Give a typical analysis of the crude sewage to which the experiment relates.

Cl., 9·0 parts per 100,000.
Ammoniacal nitrogen, 4·95 parts per 100,000.
Albuminoid nitrogen, 0·747 parts per 100,000.
Oxygen, in 4 hours, 11·15 parts per 100,000.
Suspended matter, 81·00 parts per 100,000.

(13) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.

Beds first filled Oct. 1898, and continued ever since. The beds have been rested at intervals when we have been occupied with other work, but on no occasion for more than about seven days.

(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

None made.

(15) Was any nuisance caused by the experimental works?

Absolutely none. No smell has ever been noticed on the beds.

(16) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Yes.

(17) Give particulars of any other observations of importance which were recorded.

The coarse bed was dug down to the floor of the tank after 18 months work, and no deposit was noticeable on the bottom, the clinkers were practically as clear as ever up to within 8 in. to 9 in. of the surface, and this was of a spongy nature, but having the odour of fresh garden soil.

(18) What inferences have been drawn from the experiment?

That the sewage of Maidstone is amenable to bacterial treatment.

(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

Yes.

(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

25*s*.

(*b*) What would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

8*d*.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen.
Nitric nitrogen,
Total organic nitrogen.

J. Bunting.

Signature of Officer under whose direction the experiment was conducted.

Form E. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS.

Bed A (primary) in conjunction with Bed B (secondary).

Name of authority	Manchester.
Population of district	516,000.
Water supply per head of the population	28 gallons per day.
Estimated or measured dry weather flow of sewage	21,000,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enters the sewers.
Officer under whom the experiment has been conducted.	Gilbert J. Fowler, M.Sc. (Vict.), F.I.C.
Name and qualification of chemist who has made the analyses.	W. Clifford, A.R.C.Sc.I. H. D. Bell, E. Hadfield, A. C. Oddie } Junior Assistants. Under the direction of G. J. Fowler.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse bed when filled with the filtering material?

4,530.

(*b*) What was the depth of this bed?

3 feet.

(*c*) What was the nature and size of the filtering material?

Screened clinker. Rough material round the drain pipes. Material uniform throughout the bed. Passed 3-inch mesh, rejected by 1-inch mesh.

(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.

Bed A.

Date.	Capacity in Gallons.	Remarks.
November 15th, 1898	4,530	3 hours rest.
December 14th, „	4,140	4½ hours rest.
January 10th, 1899	3,816	3½ hours rest.

(3) What was the water-holding capacity of coarse beds at end of experiment?

If the measurement was made after resting, please give the duration of the resting.

(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?

(*b*) What was the depth of this bed?

3 feet.

(*c*) What was the nature and size of the filtering material?

Bed B. Screened clinker. Rough material round the drain pipes. Material uniform through the bed. Passed 1-inch mesh, rejected by ¼-inch mesh.

(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.

Bed B.

Date.	Capacity in gallons.	Remarks.
November 16th, 1898	4,530	3 hours rest. (drainage pipes full).
January 10th, 1899	3,960	3 hours rest.

(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.

Appendix 9C.

(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.

Date.	Number of fillings.	Cycle.
November 17th, 1898, to February 8th, 1899.	3	(*a*) $\frac{3}{4}$, (*b*) 1 hour, (*c*) $\frac{3}{4}$, (*e*) 4 hours. (*a*) $\frac{3}{4}$, (*b*) 2 hours, (*c*) $\frac{3}{4}$, (*e*) $2\frac{1}{2}$ hours. (*a*) $\frac{3}{4}$, (*b*) 2 hours, (*c*) $\frac{3}{4}$, (*e*) 8 hours.
February 8th to February 15th, 1899.	4	Time of filling 6 a.m. to 12 noon, and 6 p.m. to 12 midnight. Cycle. (*a*) $\frac{3}{4}$, (*b*) 2 hours, (*c*) $\frac{3}{4}$, (*e*) $2\frac{1}{2}$ hours.

(7) State by what method the settled sewage was distributed on the beds.

By wooden shoots, perforated at the bottom of the sides.

(8) What was the average quantity of sewage in gallons dealt with daily?

10,970 (allowing for Sunday's rest).

(9) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily, except Sundays. Samples shaken before analysis.

(11) Give (*a*) the average of the analyses of the final effluent from the beds.

The following numbers are the average of daily analyses of final effluent (Bed B):—

Four hours oxygen absorption - - -	1·18
Incubator test, 3 mins. oxygen absorption, before - - - - - - -	·63
Incubator test, 3 mins. oxygen absorption, after - - - - - - -	·54
Putrescibility - - - - - -	23/237
Ammoniacal nitrogen - - - -	·69
Albuminoid nitrogen - - - - - -	·075
Nitrous nitrogen - - - - -	·021
Nitric nitrogen - - - - - -	·293
Chlorine - - - - - - - -	13·3

(*b*) the best analysis of the final effluent and date when sample was taken; and

(*c*) the worst analysis of the final effluent and date when sample was taken.

(*d*) the average of the estimations made of the solids in suspension in the settled sewage as it went on to the coarse bed.

About 41 parts per 100,000. (Data limited).

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

About 2·8 parts per 100,000.

(12) Give a typical analysis of the crude sewage to which the experiment relates.

The following members are the average of daily analyses of *settled sewage* for the quarter ending December 28th, 1898:—

4 hours oxygen absorption - - -	7·21
3 minutes oxygen absorption - - -	3·86
Ammoniacal nitrogen - - - -	2·27
Albuminoid nitrogen - - - -	·33
Chlorine - - - - - - -	16·0

(13) Between what dates was the experiment conducted?

November 10th, 1898, to February 15th, 1899.

If there were any periods of rest, state their duration.

Rested every Sunday, and one day on December 24th, 1898.

(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

(15) Was any nuisance caused by the experimental works?

No.

(16) Is the experiment still proceeding?

No.

If so, may the Commission inspect the works, should they deem it desirable to do so?

Appendix 9C.

(17) Give particulars of any other observations of importance which were recorded.	A considerable accumulation of silt occurred in the bed, the coarse clinker permitting the free access of sludge both into the body of the bed, and even into the drains below.
(18) What inferences have been drawn from the experiment?	It is not advantageous to attempt to purify sewage on contact beds without previous settlement. Further, it does not appear that material of the size of that in bed As is suited to the purpose of a contact bed, as it permits suspended matter freely to penetrate into the body of the bed, finally tending to form an almost impervious mass, which rapidly interferes with the action of the bed. In any case, even if clogging does not take place to such an extent, the suspended matter which passes away increases the burden for the secondary bed.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "Subsidence tanks" is intended to denote tanks which are used so that little or no "Septic" action is produced.

Signature of Officer under whose direction the experiment was conducted

Appendix 9C. Form E.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Wellington, Somerset, Urban Council.
Population of district	The whole district, 6,800.
Water supply per head of the population	Twenty gallons per day.
Estimated or measured dry weather flow of sewage	120,000 gallons per day in drainage area.
Is any trade refuse taken into the sewers?	None.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted.	Council's surveyor.
Name and qualification of chemist who has made the analyses.	Dr. Alford, County Analyst.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	9,380 gallons.
(*b*) What was the depth of these beds?	3 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Broken brick and tile rubble to pass a $2\frac{1}{2}$-inch ring.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No measurements taken, as beds were not considered water-tight, being simply excavations in the ground.
(3) What was the water-holding capacity of the coarse beds at end of experiment?	
If the measurement was made after resting, please give the duration of the resting.	Answer given under (2).
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Same as coarse bed after being in work about 3 weeks. At first the coarse bed more than filled the fine bed.
(*b*) What was the depth of these beds?	3 ft. 6 in.
(*c*) What were the nature and size of the filtering material?	Cinders perfectly free from dust and such as would pass a $\frac{3}{4}$-in. mesh, and rejected by a $\frac{1}{4}$-in. ditto.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not?	Answer as given under (2).
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Answer as given under (2).
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying and (*e*) resting.	Three fillings in 24 hours. The flow being intermittent, times for filling varied, but averaged 1 hour to fill, $1\frac{1}{2}$ stand full, 1 to discharge, $1\frac{1}{2}$ rest. The working was carried out at one out of several of our present outfalls.
(7) State by what method the sewage was distributed on the beds.	The sewage was distributed by open wooden trunks.
(8) What was the average quantity of sewage in gallons dealt with daily?	About 28,000 gallons.
(9) Was the quantity of sewage dealt with increased in time of storm?	
If so, state to what extent, and how the results were affected by such increase.	In times of heavy rain amounting to flood, the beds were not worked.
(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	The one sample analysed was taken directly after leaving the fine beds into the same bottle as sent to analyst without any preparation whatever.

Appendix 9C.

(11) Give (*a*) the average of the analyses of the final effluent from the beds;	Only one sample analysed (Copy of Analyst's report.) February 3, 1900. Total dissolved solids - - 33·6 grains per gallon. Chlorine in chlorides - - 4·6 " " Free ammonia - - - 0·65 per million gallons. Albuminoid ammonia - 0·20 " "
(*b*) the best analysis of the final effluent, and date when sample was taken; and	
(*c*) the worst analysis of the final effluent, and date when sample was taken;	
(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed;	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Ordinary domestic, entirely free from trade refuse.
(13) Between what dates was the experiment conducted?	March 25, 1899, and March 25, 1900.
If there were any periods of rest, state their duration.	Two days only. On days during heavy floods.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	
(15) Was any nuisance caused by the experimental works?	None whatever. The beds abutted on a public footpath, but no complaint of any kind was received during the whole time the beds were in work.
(16) Is the experiment still proceeding? - - - -	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(17) Give particulars of any other observations of importance which were recorded.	The effluent after the first two months was at all times as clear as pump water, and entirely free from smell. Samples were taken every month, which samples were dated and kept but not analysed. I noticed that whereas for the first three weeks or a month the sewage in rough bed more than filled the fine one—after which it only filled it to a little under the surface of medium.
(18) What inferences have been drawn from the experiment?	I consider it is a successful mode of treatment. Moreover I had an examination made of both beds after stopping work a few days, by having a large hole taken out in each and found that there was entire absence of any sludge, either adhering to the filtering medium or in the bottom of the beds.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes, I think it would.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers?	We shall have to lift the sewage about 60 ft., and I estimate the cost approximately at 30*s.* per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan?	Cannot speak with any accuracy, but I am of opinion the cost would not exceed 1*s.* per head.

Note.—It is requested that all analyses may be stated in parts per 100,000, and the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

E. T. HOWARD.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

Form E.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	County Borough of West Bromwich.
Population of district	In 1891, 59,489.
Water supply per head of the population	About 20 gallons per day.
Estimated or measured dry weather flow of sewage	About 1,250,000 gallons per day, total from both levels.
Is any trade refuse taken into the sewers?	Practically none.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Wholly excluded.
Officer under whom the experiment has been conducted	Borough Engineer and Surveyor.
Name and qualification of chemist who has made the analyses.	H. Silvester, F.I.C., F.C.S., Borough Analyst.
(1) (a) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	About 52,500 gallons, taking it at one-third the capacity of bed.
(b) What was the depth of these beds?	Average 3 feet 6 inches.
(c) What were the nature and size of the filtering material?	Screened engine ashes ½-inch to 2-inch mesh.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	After the beds had worked for 12 months, during which time they dealt with 813 fillings, a Siemens patent meter was fixed at the outlet and readings taken. The beds had not rested except on Sundays. It should here be stated that the low level sewage flows direct from the sewer on to the beds, there being no detritus tanks, consequently a large quantity of mineral matter finds its way into the beds.
(3) What was the water-holding capacity of the coarse beds at end of experiment?	After 12 months 29,455 gallons average of 12 readings.
If the measurement was made after resting, please give the duration of the resting.	
(4) (a) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	About 45,000 gallons, taking it at one-third the capacity of bed.
(b) What was the depth of these beds?	Three feet average.
(c) What were the nature and size of the filtering material?	Screened engine ashes ¼-inch to ½-inch mesh.
(5) (a) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	The meter was fixed to this bed after 12 months working.
(b) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	33,337 gallons, average of 12 readings.
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Three fillings every 24 hours, Sundays excepted, (*a*) 1½ hours, (*b*) 2 hours, (*c*) emptying, 1½ hours, resting 3 hours every 8 hours.
(7) State by what method the sewage was distributed on the beds.	By iron troughs 15 inches wide.
(8) What was the average quantity of sewage in gallons dealt with daily?	Estimated at 150,000 gallons at commencement.
(9) Was the quantity of sewage dealt with increased in time of storm?	No
If so, state to what extent, and how the results were affected by such increase.	

Appendix 9C.

ANALYSES of SAMPLES of SEWAGE and EFFLUENTS after Bacteria Treatment from Friar Park Sewage Farm, West Bromwich, by *H. Silvester*, F.I.C., F.C.S., Borough Analyst.

Appendix 9C.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Samples were analysed at various dates between November 6th, 1899, to September 26th, 1900, 18 in all.
(11) Give (*a*) the average of the analyses of the final effluent from the beds;	*See* table at page .
(*b*) the best analysis of the final effluent and date when sample was taken; and (*c*) the worst analysis of the final effluent and date when sample was taken;	*See* table at page .
(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed;	77·39 parts per 100,000 or 54·17 grains per gallon.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	·95 parts per 100,000 or ·66 grains per gallon. Non-putrescible.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	*See* foregoing tables.
(13) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	Commenced October 3rd, 1899, and extended to November 1st, 1900; beds rested from December 5th to 12th, 1899, and Sundays.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	*See* table at page .
(15) Was any nuisance caused by the experimental works?	None whatever.
(16) Is the experiment still proceeding? - - - -	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes, only too pleased.
(17) Give particulars of any other observations of importance which were recorded.	*See* report.
(18) What inferences have been drawn from the experiment?	The final effluent is clear, entirely without odour, remains perfectly sweet on keeping, is not liable to secondary offensive or putrefactive decomposition, and is fit to discharge into the River Tame. However small the relative volume, the effluents have always been better than the water in the River Tame, and would improve the river, and there is no doubt that the whole of the sewage of West Bromwich can successfully be treated by this system without the aid of land.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	A scheme has been prepared for dealing with the whole of the sewage of the borough and adopted by the Council.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers;	About 5s.; this includes detritus tanks.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	About a halfpenny per head if the effluents could go direct from the fine beds into the stream, if they had to be pumped back on to the land it would increase the cost to 2½d. per head, excluding any annual charges on the machinery.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

ALBERT D. GREATOREX, Assoc. M. Inst. C. E.,
Borough Engineer and Surveyor.

Signature of Officer under whose direction the experiment was conducted.

Form E.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Wigston Magna Urban District Council.
Population of district	9,048 (estimated).
Water supply per head of the population	12½ gallons per day (estimated).
Estimated or measured dry weather flow of sewage?	121,815 gallons per day (measured).
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes, from dye works, about 1·64 per cent.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Very little excluded, except during a severe storm, when the overflow chamber is then in use.
Officer under whom the experiment has been conducted	Surveyor to the Council.
Name and qualification of chemist who has made the analyses.	Dr. C. Coles, M.D., D.P.H., Medical Officer of Health and Analyst to the Council.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	3,172 gallons, when it commenced to overflow.
(*b*) What was the depth of these beds?	4 feet, *i.e.*, six inches above invert of overflow pipe.
(*c*) What were the nature and size of the filtering material?	¾-inch burnt (ballast) clay.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	None made.
(3) What was the water-holding capacity of the coarse beds at end of experiment?	3,011 gallons, when it commenced to overflow.
If the measurement was made after resting, please give the duration of the resting.	After 17 hours resting.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	No measurement made. It was constructed the same size as the coarse bed, and was then sufficiently large to take the whole of the effluent from the coarse bed, without overflowing.
(*b*) What was the depth of these beds?	4 feet, *i.e.*, six inches above invert of overflow pipe.
(*c*) What were the nature and size of the filtering material?	½-inch cinder to 3 feet 6 inches in depth, then covered to 6 inches in depth with ½-inch burnt ballast.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	None made.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	None made.
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Fillings 1·52 on the average per diem. (*a*) Average time to fill bed about 2½ hours. (*b*) Two hours. (*c*) Seventy minutes. (*e*) Two hours after each emptying (also each night and each Sunday).
(7) State by what method the sewage was distributed on the beds.	By wooden troughs.
(8) What was the average quantity of sewage in gallons dealt with daily?	4703·5 gallons.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	The contact beds were not used in time of storm on account of the road detritus that would be washed from the macadamized roads into the sewers.

Appendix 9C.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Analyses were made at no definite intervals. Samples shaken up—not filtered—so as to get fair specimens.
(11) Give (*a*) the average of the analyses of the final effluent from the beds ;	Oxygen absorbed in 4 hours at 80° F. 1·39 parts per 100,000.
(*b*) the best analysis of the final effluent and date when sample was taken ; and	13th December 1899. Sewage, 7·6 parts oxygen absorbed per 100,000. Final effluent, ·33 ,, ,, ,, ,, ,, = 95·6 per cent. reduction.
(*c*) the worst analysis of the final effluent and date when sample was taken ;	23rd September 1899. Sewage :—9·45 parts oxygen absorbed per 100,000. Effluent, 3·42 ,, ,, ,, ,, ,, = 63·8 per cent. reduction.
(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed ;	None made.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible ?	None made.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Oxygen absorbed. Parts per 100,000. Sewage, 9·16. Effluent, coarse bed, 3·6. ,, fine bed, 2·23. Strong sewage. Sewage, 3·8. Effluent, coarse bed, ·82. ,, fine ,, ·67 Weak sewage.
(13) Between what dates was the experiment conducted ?	March 1899 and October 1900.
If there were any periods of rest, state their duration.	Seven days beside each night and each Sunday.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None made.
(15) Was any nuisance caused by the experimental works ?	No.
(16) Is the experiment still proceeding ?	The contact beds are still being used and work satisfactorily.
If so, may the Commission inspect the works, should they deem it desirable to do so ?	Yes.
(17) Give particulars of any other observations of importance which were recorded.	
(18) What inferences have been drawn from the experiment ?	That the method tried gives good results for average strengths of sewage. That the final effluent of an average sewage is fit to pass into a stream. That a collection of sewage should be made in a large tank open or closed so as to give a fair average strength of sewage for treatment in the contact beds.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Yes.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	Approximate estimate from 14*s*. to 16*s*. per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	From 6*d*. to 9*d*. per head.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Only oxygen absorbed from permanganate used for determining the purification of the sewage.

WM. GEO. J. CLARK.
Signature of Officer under whose direction the experiment was conducted.

Form E. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Withington Urban District Council.
Population of district	Estimated at 36,000. Adjoining district of Levenshulme, 12,000, also received and dealt with at our sewage works.
Water supply per head of the population	About 30 gallons per day.
Estimated or measured dry weather flow of sewage	About 2,500,000 gallons per day, of which 1,000,000 gallons is subsoil water from old sewers, etc.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	A small quantity from Levenshulme Bleach Works, but quantity may be neglected.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Practically the whole of the roof and surface water is taken into the sewers.
Officer under whom the experiment has been conducted.	Surveyor to the Urban District Council
Name and qualification of chemist who has made the analyses.	C. Estcourt, Esq., City Analyst, Manchester.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	56 per cent., or 20,317 gallons.
(*b*) What was the depth of these beds?	2·25 ft.
(*c*) What were the nature and size of the filtering material?	Crushed clinker from destructor averaging 1 to 2 ins. longest measure.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	No experiments made.
(3) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	56 per cent., or 20,317 gallons.
(*b*) What was the depth of these beds?	2·25 ft.
(*c*) What were the nature and size of the filtering material?	Crushed clinker from destructor averaging ¼ to 1 in., longest measure.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	No experiments made.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	
(6) State method of working of contact beds, *i.e.*, number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	2 fillings per diem—in 12 hours; 1 hour filling, 2 hours standing full, 1½ hours emptying, 2 hours resting.
(7) State by what method the sewage was distributed on the beds.	By wooden troughs.
(8) What was the average quantity of sewage in gallons dealt with daily?	40,634 gallons.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No experiments made.

Appendix 9C.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Once only on 3rd August, 1899.
(11) Give (*a*) the average of the analyses of the final effluent from the beds ; (*b*) the best analysis of the final effluent and date when sample was taken ; and (*c*) the worst analysis of the final effluent and date when sample was taken ; (*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed ; (*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	See table below. The foregoing results show this effluent is sufficiently pure to be well within the limits of pollution laid down by the Mersey and Irwell Joint Committee by sewage effluents.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	None.
(13) Between what dates was the experiment conducted? If there were any periods of rest state their duration.	None.
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	None.
(15) Was any nuisance caused by the experimental works?	None.
(16) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(17) Give particulars of any other observations of importance which were recorded.	None.
(18) What inferences have been drawn from the experiment?	That the "Bacterial" treatment is satisfactory as far as can be judged from the analysis.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.	About £2 per head.
(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.	About 7*d*. per head.

—	Grains per gallon.
Chlorine, combined	4·26
Meal ammonia	0·4750
Albuminoid ammonia	0·520
Nitrogen as nitrites and nitrates	0·060
Oxygen absorbed in 4 hours	0·332
Total solid matter at 212° F.	38·00
Mineral solid matter on ignition	20·00
Volatile matter	18·00
Appearance slightly opalescent	
To test paper slightly alkaline	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

A. H. Mountain, Surveyor.

Signature of Officer under whose direction the experiment was conducted.

Form E. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Urban District Council of Withnell.
Population of district	3,750 (estimated).
Water supply per head of the population	Nine gallons per day.
Estimated or measured dry weather flow of sewage	25,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Yes.
Officer under whom the experiment has been conducted.	T. Beaver, Surveyor.
Name and qualification of chemist who has made the analyses.	None made.
(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	5,000 gallons.
(*b*) What was the depth of these beds?	3 feet 3 inches.
(*c*) What were the nature and size of the filtering material?	Furnace ashes. To pass a 2-inch mesh retained on a 1-inch mesh.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	None made.
(3) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	None made.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	5,500.
(*b*) What was the depth of these beds?	3 feet 3 inches.
(*c*) What were the nature and size of the filtering material?	To pass 1-inch mesh and retained on ½-inch mesh.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	None made.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	None made.
(6) State method of working of contact beds, *i.e.*, number of fillings per day of 24 hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	Two fillings per day. (*a*) Two hours. (*b*) Two hours (*c*) One hour. (*e*) Two hours.
(7) State by what method the sewage was distributed on the beds.	By means of wood troughs.
(8) What was the average quantity of sewage in gallons dealt with daily?	10,000 gallons.
(9) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No; passed on to land.

Appendix 9C.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	None made.
(11) Give (*a*) the average of the analyses of the final effluent from the beds.	Not known.
(*b*) The best analysis of the final effluent and date when sample was taken, and	
(*c*) The worst analysis of the final effluent and date when sample was taken.	Not known.
(*d*) The average of the estimations made of the solids in suspension in the sewage as it went on to the coarse bed.	Not known.
(*e*) The average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?	Not known.
(12) Give a typical analysis of the crude sewage to which the experiment relates.	Domestic sewage.
(13) Between what dates was the experiment conducted?	May 1899 to date.
If there were any periods of rest, state their duration.	
(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.	Not taken.
(15) Was any nuisance caused by the experimental works?	No.
(16) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(17) Give particulars of any other observations of importance which were recorded.	
(18) What inferences have been drawn from the experiment?	That it is a good preliminary treatment before passing the sewage on to land.
(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	£1 per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	6*d*. per head.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus:

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

THOMAS BEAVER.
Signature of Officer under whose direction the experiment was conducted.

Form E.

Appendix 9C.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE IN CONTACT BEDS. (DOUBLE CONTACT.)

Name of authority	Corporation of York.
Population of district	About 75,000.
Water supply per head of the population	33 gallons per day.
Estimated or measured dry weather flow of sewage	45 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Trade refuse is so small as to be negligible.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Storm water above the capacity of the sewers.—Yes. Soil or surface.—No.
Officer under whom the experiment has been conducted.	City engineer.
Name and qualification of chemist who has made the analyses.	(*a*) Thomas Fairley, F.I.C., F.R.S.Edin.; F.C.S. London. &c., &c. (*b*) Edmund Moody Smith, M.D., C.M.Edin.; D.P.H. Cam. Medical Officer of Health, York.

(1) (*a*) What was the water-holding capacity at commencement of experiment of the coarse beds when filled with the filtering material?	18,550 gallons.
(*b*) What was the depth of these beds?	3ft. 3in.
(*c*) What were the nature and size of the filtering material?	All rejected by $1\frac{1}{4}$ in. screen.
(2) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of coarse beds, stating in each case whether the measurement was made after resting or not.	See table below.

1899:	Gallons.	
On 13 June	18,550	—
„ 11 September	9,360	—
„ 25 September	13,650	After 14 days rest.
„ 6 November	9,600	—
„ 27 November	12,750	Rest.
„ 11 December	9,900	—
„ 26 December	11,000	58 hours rest.

* On the 1st filling after 14 days rest a large quantity of sludge was unfortunately washed out of the supply pipe on to the bed.

(3) What was the water-holding capacity of the coarse beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	It has never been less than 9,360 gallons after resting for Sunday.
(4) (*a*) What was the water-holding capacity at commencement of experiment of the fine beds when filled with the filtering material?	Not ascertained. The flow from No. 1 has never filled No. 2 more than 2 ft. in depth with liquid.
(*b*) What was the depth of these beds?	3 ft 3 in.
(*c*) What were the nature and size of the filtering material.	Clinker and coke $\frac{3}{8}$ to $\frac{7}{8}$ in.
(5) (*a*) Give particulars of measurements made from time to time during the experiment of the water-holding capacity of the fine beds, stating in each case whether measurement was made after resting or not.	Not ascertained. The effluent from No. 1 bed only filled No. 2 for about two ft. in depth, and on no occasion has it been necessary to fork over the surface.
(*b*) What was the water-holding capacity of fine beds at end of experiment? If the measurement was made after resting, please give the duration of the resting.	Not ascertained, The surface of this bed has remained clear of any deposit throughout.
(6) State method of working of contact beds, *i.e.* number of fillings per day of twenty-four hours, and periods of (*a*) filling, (*b*) standing full, (*c*) emptying, and (*e*) resting.	8 hour cycles: (*a*) $1\frac{1}{4}$ filling, (*b*) 2 standing full (*c* and *e*) $4\frac{3}{4}$ hours.

Appendix 9C.

(7) State by what method the sewage was distributed on the beds.

Run on in semi-circular glazed drain pipes.

(8) What was the average quantity of sewage in gallons dealt with daily?

About 33,000 gallons.

(9) Was the quantity of sewage dealt with increased in time of storm?

If so, state to what extent, and how the results were affected by such increase.

No.

(10) State at what intervals analyses of the effluent were made and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Weekly, monthly, and at longer intervals. Allowed to clear by standing.

(11) Give (*a*) the average of the analyses of the final effluent from the beds.

Total solids	72·58
Mineral matter	67·58
Volatile and organic matter	5·0
Free ammonia	1·21
Albuminoid ammonia	·145
Nitrogen as calcium nitrate	Nil.
Nitrogen as nitrites	Nil.
Oxygen required to oxidise organic matter in 4 hours.	·643
Reaction	Alkaline.
Chlorine	12·15
Sediment	·096
Analyst	Mr. Fairley.

(*b*) the best analysis of the final effluent and date when sample was taken, and

(*c*) the worst analysis of the final effluent and date when sample was taken.

—	Best. 22 November, 1899. Bed No. 1.	Best. 22 November, 1899. Bed No. 2.	Worst. 1 August 1899.
Total solids	99·11	95·67	79·7
Mineral matter	91·68	74·3	74·3
Volatile and organic matter	7.43	5·4	5·4
Free ammonia	2·8	1·44	1·65
Albuminoid ammonia	·186	·157	·2
Nitrogen as calcium nitrate	Nil	7·6	Under ·01
Nitrogen as nitrites	Trace	Trace	—
Oxygen required to oxidise organic matter in 4 hours	·643	·328	·957
Reaction	Alkaline	Alkaline	Alkaline
Smell (when cold)	None	None	Very faint
Chlorine	20·3	17·74	14·54
Sediment	3·88	Trace	—
Containing organic matter	2·97	Trace	—
Analyst	Mr. Fairley		

(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the coarse beds.

Not ascertained.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these putrescible?

Trace only. No.

(12) Give a typical analysis of the crude sewage to which the experiment relates.

Total solids	83·67
Mineral matter	69·51
Volatile and organic matter	14·157
Free ammonia	5·0
Albuminoid ammonia	0·7
Nitrogen as calcium nitrate	Nil.
Nitrogen as nitrites	Nil.
Oxygen required to oxidise organic matter in 4 hours	4·3
Reaction	Alkaline.
Smell (when cold)	Very offensive.
Chlorine	12·63
Sediment	30·41
Containing organic matter	21·84
Analyst	Mr. Fairley

Appendix 9C.

(13) Between what dates was the experiment conducted

From June 1899 to October 1900, with crude sewage since that date with open septic tank effluent.

If there were any periods of rest state their duration.

Every Sunday.

(14) Give particulars of any observations which may have been made of the temperatures of the contact beds at different depths.

The following are typical temperatures taken at the bottom of No. 1 bed, when the outside temperature has been under 35 or over 45.

Date.	Hour.	Atmosphere.	Bed.	Date.	Hour.	Atmosphere.	Bed.
1900 : 29 November -	10 a.m.	46	47	1900 : 29 December -	9 p.m.	31	42
11 December -	9 a.m.	46	45	1901 : 1 January -	9 p.m.	30	40

(15) Was any nuisance caused by the experimental works?

No.

(16) Is the experiment still proceeding?

Terminated in October last

If so, may the Commission inspect the works should they deem it desirable to do so?

Yes.

(17) Give particulars of any other observations of importance which were recorded.

The first bed had to be forked over from time to time, and on one occasion about ¾ of a cubic yard of solid matted matter was removed from the surface.

(18) What inferences have been drawn from the experiment?

That this method is superior to chemical precipitation, but not equal to open septic tank treatment followed by continuous filtration.

(19) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state.

It is practicable but is not considered expedient in view of the superior results obtained by experiment referred to in form G.

(*a*) What would be the estimated capital cost per head of constructing the works of disposal—excluding the cost of land and cost of sewers.

(*b*) What would be the estimated annual cost per head of purifying the sewage by this system—excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be stated in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

This cannot now be done, the analyses are given as received. A standard form for sewage analyses is very much needed.

A. Creer.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form G.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	Acton District Council.
Population of district - - - - - - -	About 36,000. The drainage from about 18,000 persons goes to the Council's Sewage Works, all other drainage to the Sewers of the London County Council.
Water supply per head of the population - - -	
Average measured dry weather flow of sewage - -	674,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Hardly any trade refuse except the waste waters from laundries, of which there are a great number.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Only partially.
Officer under whom the experiment has been conducted.	The surveyor, assisted recently by the Medical Officer of Health.
Name and qualification of chemist who has made the analyses.	E. J. Bevan, Esq., analyst to County Council of Middlesex.
(1) (*a*) What is the capacity in gallons of the open septic tank?	146,000 gallons.
(*b*) If there was more than one tank state whether they were worked in series or in parallel.	One tank only.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	Tank first in use October 4th, 1899, and on December 20th, 1900, there was found to be a deposit at the inlet end of tank about ¼ inch thick, consisting of grit, and no deposit was found at the other end.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	No removal.
(3) (*a*) What are the form, the area and depth of the filters?	Octagonal area 66 yards superficial average depth when analysis was taken 6 feet 6 inches, afterwards increased. *See answer to Q.* 10.
(*b*) State the nature and size of the filtering material	Broken clinker about 2 inch gauge.
(*c*) Were the sides of the filters open or closed? -	Open.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	500 gallons per square yard per 24 hours.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Not reduced, except as mentioned in answer to Q. 15.
(5) What was the average quantity of sewage in gallons dealt with daily?	Amount filtered, 33,000 gallons per 24 hours.
(6) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	No, though the sewage would be diluted.
(7) State by what method the tank liquor was distributed on the filters.	By revolving sprinklers (Whittaker and Bryant's.)
(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	One analysis only taken. A sample was taken every hour for 12 hours on one day, the samples mixed, and a gallon of the mixture was sent to the analyst.
(9) Give (*a*) the average of the analyses of the final effluent from the filters.	Analysis by Mr. E. J. Bevan on March 27th, 1900. (see below) This is the only analysis taken.
(*b*) the best analysis and date when sample was taken, and	
(*c*) the worst analysis and date when sample was taken	
(*d*) solids in suspension in the tank liquor as it went on to the filters	1·50 on March 27th 1900.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	

	parts per 100,000.
Total solids in solution - - - - -	84·7
Solids in suspension - - - - -	traces
Chlorine - - - - - - - -	7·5
Free ammonia - - - - - - -	1·15
Albuminoid ammonia - - - - -	·075
Oxygen absorbed - - - - - -	·54
Appearance - - - - - - -	clear
Smell - - - - - - - -	none

Appendix 9C.

(10) Give a typical analysis of the crude sewage to which the experiment relates.	Analysis by Mr. E. J. Beva on March 27th 1900. parts per 100,000 Total solids in solution - - - - - 85·0 Solids in suspension - - - - - 47·4 Chlorine - - - - - - - - 7·8 Free ammonia - - - - - - - 3·9 Albuminoid ammonia - - - - - ·335 Oxygen obsorbed - - - - - - 1·75 Appearance - - - - - - - Usual. Smell - - - - - - - - Usual.
(11) Between what dates was the experiment conducted?	
If there were any periods of rest state their duration.	
(12) Give particulars of any observations which have been made of thr temperatures of the filters at different depths.	
(13) Was any nuisance caused by the experimental works?	Complaints were last summer made as to smells from the filter. To diminish this the sewage was not allowed to rest so long in the septic tank, and the surface of the filter was raised a foot, bringing it nearer the sprinkler (the average depth of filter being now 7 ft. 6 in.) and these alterations materially diminished the smell, so that no complaints have been received since these alterations were carried out.
(14) Is the experiment still proceeding? - - - -	Yes, as also a smaller experimental filter which will probably be the model for further filters.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(15) Give particulars of any other observations of importance which have been recorded.	When the filter was started on October 4th, 1899, the sewage was allowed 106 hours to flow through the septic tank on its way to the filter, and a thick crust was formed upon the sewage in tank. In the summer of 1900 when complaints were made as to smells from the filter, the speed of the revolving sprinkler was slightly reduced, and the sprinkler was stopped on two or three occasions for repairs to the ironwork, so that the flow through the septic tank was retarded. Thereupon an ebullition took place in the tank, and gas was given off in transparent bubbles (the ordinary bubbles on the crust were black leathery looking bubbles) and the crust rapidly disappeared. The speed of the sprinkler was increased, and the tank was allowed continuously to deliver into an ordinary tank (about 176,000 gallons per day) so that the sewage took only $16\frac{3}{4}$ hours to travel through the tank, and a thick crust was formed again in a few hours.
(16) What inferences have been drawn from the experiment?	That sewage can be treated in this way, even when it has to be lifted on to the filters, more economically and with less offence, than by methods of chemical precipitation. *Note.*—The effluent from the sewage works is carried direct into the tideway of the Thames at Chiswick Eyot and therefore no high degree of purification is required by the Thames Conservancy.
(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	No such estimates have been made.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

D. J. Ebbets, Surveyor.

Signature of Officer under whose direction the experiment was conducted.

Form G.

Appendix 9C.

CONTINUED EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority - - - - -	Carshalton Urban District Council.
Population of district - - - - - - - -	6,700.
Water supply per head of the population - - -	30
Measured dry weather flow of sewage - - - -	230,000.
Is any trade refuse taken into the sewers?	No.
If so state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Wholly excluded.
Officer under whom the experiment has been conducted.	Wm. Willis Gale, A.M.I.C.E.
Name and qualification of chemist who has made the analyses.	Messrs. Dibden and Thudichum, F.I.C., F.C.S.
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	77,000 gallons each tank.
(*b*) If there was more than one tank state whether they were worked in series or in parallel.	Three, worked in parallel one always being in reserve.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	The tanks have been receiving the whole of the sewage for upwards of 8 months and only a very slight deposit of sludge can be discovered.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	None removed.
(3) (*a*) What are the form, the area and depth of the filters?	Rectangular, 4 filters, 1,815 sq. yds. in each, or $1\frac{1}{2}$ acres in all; 4 ft. 6 in. in depth.
(*b*) State the nature and size of the filtering material.	Size. / Depth. Burnt ballast, sifted - - - - 1 in. 12 in. Mixed ballast, breeze and sandy soil - $\frac{1}{2}$ „ 36 „ Selected top soil - - - - - - 6 „
(*c*) Were the sides of the filters open or closed? - -	Closed, with side air inlets communicating with the underdrains of filters.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	127 gallons per yard super.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Not noticeable.
(5) What was the average quantity of sewage, in gallons, dealt with daily?	The whole daily flow of 230,000 gallons.
(6) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	No.
(7) State by what method the tank liquor was distributed on the filters.	By open half pipe channels with non stops for equal distribution.
(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Only one analysis made for the character of the effluent is apparent to the eye.
(9) Give (*a*) the average of the analyses of the final effluent from the filters.	Appearance - - - - Clear and bright. Odour - - - - - - Nil. Reaction - - - - - Very faintly alkaline. Chlorine - - - - - 9·71 parts per 100,000 Ammoniacal nitrogen - - ·204 „ „ „ Albuminoid „ - - ·03 „ „ „ Oxygen at once - - - Trace. „ „ in 4 hours - - - ·44 „ „ „ Nitrous nitrogen - - - Trace. Nitric nitrogen - - - 7·294 parts per 100,000 Suspended matters - - - Slight traces. „ „ volatile - „ „ Dissolved solids, total - - 144·57 parts per 100,000 „ „ volatile - - 60·14 „ „ „
(*b*) the best analysis and date when sample was taken and	10th September, 1900.

(c) the worst analysis and date when sample was taken.	10th September, 1900.
(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters.	Not taken.
(e) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	Slight trace.
(10) Give a typical analysis of the crude sewage to which the experiment relates.	Oxygen absorbed ¼ hour - - 5·757 parts per 100,000 " " 4 " - - 12·90 " " " Chlorine - - - - - 10·857 " " " Ammoniacal nitrogen - - 10·90 " " " Albuminoid " - - 2·58 " " "
(11) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	No 1 tank has been in use since March, 1900. No 2 tank has been in use since May, 1900.
(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	None made.
(13) Was any nuisance caused by the experimental works?	When the sewage is pumped into the septic tanks a smell of sulphuretted hydrogen is apparent.
(14) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	This is not strictly speaking an experiment, for the whole of the sewage is treated on these lines. Yes.
(15) Give particulars of any other observations of importance which have been recorded.	That the effluent absorbed impurities after passing over land. It was noticed within 8 or 9 days after these tanks were started that black masses of sludge arose from the bottom of the tanks, accompanied by bubbles of gas. After some months had elapsed these masses of sludge formed a compact and practically air-tight cover to the sewage in the tanks. This only occurred in the first two divisions, it being a difficult matter to get a scum to form on the third or last division in the tank. (Each tank is practically three tanks on account of the floating scum boards.) In frosty weather a scum arises in the last division which disperses shortly after the sun has shone on it. The inference to be drawn from this fact is that the changes going on in the body of the tanks provide automatically as it were a protection from climatic changes, so that the sewage remains in an equable condition as regards temperature. The gas bubbles can be easily ignited, and burn for a short time with energy.
(16) What inferences have been drawn from the experiment?	That the sewage by simply passing through the tanks with its three divisions is purified to the extent of 46 per cent., taking the oxygen absorbed test as a guide, and to the extent of 64 per cent. by the albuminoid ammonia test, and that nearly all the solid organic matter is digested and liquefied, the tank effluent then being in such a condition that the further treatment in the filter bed is considerably assisted.
(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	The whole of the sewage is now being disposed of on the lines of this system.
(a) the capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	17s., made up as follows:— £ s. d. 1,597 0 3 Tanks. 472 13 6 Sludge well. 3,622 11 11 Filters. 5,692 5 8
(b) the annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	1/7·27*d*.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Wm. Willis Gale, A.M.I.C.E.
Signature of officer under whose direction the experiment was conducted.

Appendix 9C. Form G.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	Mayor, Aldermen, and Burgesses of the Borough of Hyde.
Population of district - - - - - - -	Estimated at 32,000.
Water supply per head of the population - - -	20 gallons per day for a population of 30,000 supplied.
Estimated or measured dry weather flow of sewage -	1,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Hat works, margarine works, india-rubber works, aniline dye works, slaughter houses, tripe boiling works, &c., estimated at 25,000 gallons.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted.	Mr. T. Carter Beeley (Mayor and Chairman of Committee), under the advice of Mr. F. Scudder.
Name and qualification of chemist who has made the analyses.	Mr. Frank Scudder, F.I.C.
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	75,000.
(*b*) If there was more than one tank state whether they were worked in series or in parallel.	One only.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	Tank was emptied after 14 months work, the sludge remaining was 11 tons (the weekly quantity under chemical precipitation).
(3) (*a*) What are the form, the area and depth of the filters?	Whittaker and Bryant system. Circular, 43 feet diameter and 9 feet deep.
(*b*) State the nature and size of the filtering material.	Coke refused by 2 inch ring.
(*c*) Were the sides of the filters open or closed?	Open under bottom, and open for 4 feet from top all round.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	600 gallons for 3 months, since that time 450 gallons.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Reduction was not due to choking, but to obtain a better result. The alteration had immediate success.
(5) What was the average quantity of sewage in gallons dealt with daily?	75,000 gallons.
(6) Was the quantity of sewage dealt with increased in time of storm?	Constant volume taken daily into septic tank.
If so, state to what extent, and how the results were affected by such increase.	No increase taken.
(7) State by what method the tank liquor was distributed on the filters.	By revolving sprinklers (automatic), liquor being pumped from tank by pulsometer pump, Whittaker and Bryant's principle.
(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper, or allowed to clear by standing, before being analysed.	Weekly, by Whittaker and Bryant, Accrington, at frequent intervals by Mr. F. Scudder, analyst to the Mersey and Irwell Board.
(9) Give (*a*) the average of the analyses of the final effluent from the filters.	(*a*) Ammoniacal nitrogen, 0·62 parts per 100,000. Albuminoid nitrogen, 0·20 „ „ Residual nitrogen, not determined. Nitrous nitrogen, 0·17 parts per 100,000. Nitric nitrogen, 1·20 „ „ Oxygen absorbed 3 minutes test, 0·60 „ „ 4 hours test, 1·63 „ „ Transparency millimetres seen through, 154. Chlorine (Cl.), 26·3 parts per 100,000.
(*b*) the best analysis and date when sample was taken, and	July 5th, 1900. Ammoniacal nitrogen, 0·52 parts per 100,000. Albuminoid nitrogen, 0·17 „ „ Nitrous nitrogen, 0·16 „ „ Nitric nitrogen, 1·10 „ „ Oxygen absorbed— 3 minutes test, 0·43 „ „ 4 hours test, 1·20 „ „ Transparency millimetres seen through, 232. Chlorine (Cl.), 20·0 parts per 100,000.

Appendix 9C.

(c) the worst analysis and date when sample was taken ;	July 11th, 1899. Parts per 100,000 Ammoniacal nitrogen - - - - - 3·30 Albuminoid „ - - - - - - 0·41 Nitrous „ - - - - - - None. Nitric „ - - - - - - None. Oxygen absorbed— 3 minutes test - - - - - 1·4 4 hours test - - - - - - 2·60 Transparency millimetres seen through - 97 Chlorine (Cl.) - - - - - - 22·0
(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters ;	4 grains mineral. 5 grains organic. Total 9 grains per gallons.
(e) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible ? No.	1·7 grain mineral. 2·6 grain organic. 4·3 grains total per gallon.
(10) Give a typical analysis of the crude sewage to which the experiment relates.	Ammoniacal nitrogen, 4·80 parts per 100,000. Albuminoid nitrogen, 2·00 „ „ Oxygen absorbed— 3 minutes test, 3·63 „ „ 4 hours test, 11·40 „ „ Transparency, 20·0 „ „ Chlorine, 22·5 „ „
(11) Between what dates was the experiment conducted ?	June 24th, 1899, to present date.
If there were any periods of rest, state their duration.	Since October, 1900, rested nightly four to five hours, with improved results.
(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	Not taken. Temperature of water falling on averages 55° F.
(13) Was any nuisance caused by the experimental works ?	Not received any complaints.
(14) Is the experiment still proceeding ?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so ?	Yes.
(15) Give particulars of any other observations of importance which have been recorded.	The filter appears to have periodical slight floodings, causing pools in different parts of the filter. These always disappear in three or four days without slowing down the filter. There is a slight deposit in the final effluent, which slightly affects the analyses. This we are arranging to take out. We found it was not possible to press the sludge at the stoppage. It was so greasy (apparently) that the press cloths were coated over and refused to pass the liquid through.
(16) What inferences have been drawn from the experiment ?	We have, under the advice of Mr. F. Scudder and Messrs. Dibdin and Thudichum, and encouraged by the excellent results obtained, drawn out a complete scheme on this principle, and applied to the Local Government Board for powers. Colonel Marsh and Dr. Buchanan were the inspectors, and complete evidence was laid before them. Their decision has not yet been received.
(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(a) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers;	13*s.* 7*d.* per head. In addition to the money previously spent on chemical precipitation system, much of which will be again available.
(b) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	10*d.* per head.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

T. C. Beeley (Mayor),

Signature of Officer under whose personal direction the experiment was conducted.

Appendix C Form G.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWING BY CONTINUOUS FILTRATION. (BED B.)

Name of authority	Manchester.
Population of district	550,000.
Water supply per head of the population	Gallons per day Domestic use - 17 Trade purposes - 11 Total - 28
Estimated or measured dry weather flow of sewage	27,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers.	Mostly enter the sewers. Storm overflows are provided at certain points which are supposed to come into action at a dilution of five to one; in certain cases however they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc. (Vict.), F.I.C. (Supt.)
Name and qualification of chemist who has made the analyses.	Edward Ardern, B.Sc. (Vict.) H. A. Bell, A. C. Oddie E. Hadfield, Junior Assistants. Under the direction of G. J. Fowler (Supt.)
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	1,125,000 gallons.
(*b*) If there was more than one tank state whether they were worked in series or in parallel.	
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	
If the sludge was removed from the Septic Tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What are the form, the area and depth of the filters?	Square, with sloping sides. 3 ft. deep. Area at top . Area at bottom 17 ft. 6 in. square.
(*b*) State the nature and size of the filtering material	Clinker. Passed 1-in. mesh, rejected by ¼-in., with rough material round the drain.
(*c*) Were the sides of the filters open or closed?	Closed.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	245 gallons per square yard per 24 hours. (Allowing for Sunday's rest.)
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	In consequence of impurity of filtrates, the method of working was altered from 12 hours continuous flow per day (February 28—March 22) to alternate periods of two hours flow, and two hours rest. (March 22—April 25).
(5) What was the average quantity of sewage in gallons dealt with daily?	15,656 gallons (after allowing for Sunday's rest).
(6) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	

Appendix 9C.

(7) State by what method the tank liquor was distributed on the filters.

Specially-constructed wooden shoots laid on the surface of the bed were employed, having bevelled edges, over which the open septic tank effluent passed in a thin stream, reaching the filter in drops. Considerable difficulty was experienced in getting the shoots level.

(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.

Daily except Sundays. Samples shaken before analysis.

(9) Give (*a*) the average of the analyses of the final effluent from the filters;

The following numbers are the average of daily analyses for the periods given :—

DATE.	Four hours Oxygen Absorption.	Incubator Test. Three Minutes Oxygen Absorption. Before.	After.	Putrescibility.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
28 February to 22 March 1900, 12 hours continuous flow and 12 hours rest during the day.	5·10	3·17	3·48	16–17	1·64	·162	·053	·193	17·1
22 March to 25 April 1900, alternate periods of two hours rest and work.	5·80	3·13	4·01	27½–28	3·09	·29	·037	·085	16·3

(*b*) the best analysis and date when sample was taken; and

(*c*) the worst analysis and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;

17·0 to 18·0 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?

Very fair amount. Yes.

(10) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of *Settled Sewage* for the half-year ending June 27th, 1900 :—

4 hours oxygen absorption	7·86
3 minutes oxygen absorption	3·93
Ammoniacal nitrogen	1·91
Albuminoid nitrogen	·335
Chlorine	16·3

(11) Between what dates was the experiment conducted?

From February 28th to April 25th, 1900.

If there were any periods of rest, state their duration.

Rested on Sundays.

(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths.

(13) Was any nuisance caused by the experimental works?

No.

(14) Is the experiment still proceeding?

No.

If so, may the Commission inspect the works, should they deem it desirable to do so?

(15) Give particulars of any other observations of importance which have been recorded.

(16) What inferences have been drawn from the experiment?

That an arrangement such as that described does not appear to offer any advantage over the ordinary method of intermittent filtration.

Appendix 9C.

(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—

(a) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers;

(b) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

Note.—It is requested that all analyses may be stated in parts per 100,000, an that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

GILBERT J. FOWLE .

Signature of Officer under whose direction the experiment was conducted.

Form G. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTICK TANK FOLLOWING BY CONTINUOUS FILTRATION. (STODDART FILTER.)

Name of authority - - - - - - - -	Manchester.
Population of district - - - - - -	543,902.
Water supply per head of the population - - -	28 gallons per day; 17 domestic use, 11 trade purposes.
Estimated or measured dry weather flow of sewage -	27,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Breweries, dye and bleach works, galvanising works, grease refineries, tanneries, manufactories of tar products rubber goods works, tripe-dressing works, mineral water manufactor. About 4 to 5 per cent.
Is the storm, soil or surface water, wholly or partially excluded from the ordinary sewers?	Mostly enters the sewers. Storm overflows are provided at various points which are supposed to come into action at a dilution of 5 to 1; in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted,	Gilbert J. Fowler, M.Sc. (Vict.), F.I.C. (Superintendent)
Name and qualification of chemist who has made the analyses.	Laboratory Staff: Edward Ardern, B.Sc. (Vict.), ; H. D. Bell, A. Oddie, E. Hadfield, junior assistants, under the direction of G. J. Fowler, Superintendent.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	125,000 gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	
(2) Were any observations made as to the filling up of the septic tanks by the deposit of sludge?	Yes.
If the sludge was removed from the septic tanks, state how often this was done, and, approximately, what quantity of sludge was removed on each occasion.	
(3) (*a*) What are the form, the area and depth of the filters?	Rectangular, surface area 16 square yards, depth 6 feet.
(*b*) State the nature and size of the filtering material	Chiefly large clinker, top coat of coke both 3 in. by 2 in.
(*c*) Were the sides of the filters open or closed? -	For the most part the sides were of boarding, spaces of about an inch being left between the boards. The filter being constructed near a bank some excavation was necessary and the base of the filter was surrounded by earth to a depth varying roughly from 1 to 2 ft. This was aferwards cut completely away on two sides, but the filtrate at all times could flow freely away through the 2-in. pipes into a manhole.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	240 gallons.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	The rate of flow had on several occasions to be reduced on account of the quality of the filtrate.
(5) What was the average quantity of sewage in gallons dealt with daily?	3,840 gallons.
(6) Was the quantity of sewage dealt with increased in time of storm?	Not appreciably.
If so, state to what extent, and how the results were affected by such increase.	

Appendix 9C.

(7) State by what method the tank liquor was distributed on the filters.

By means of Stoddart's patent distributor. The tank effluent flows into a supply channel of cast iron and thence along perforated gutters of corrugated zinc. The perforations are cut in diamond shape at intervals along the upper edges of the corrugation. Through the lower edges small holes are made which admit ordinary nails, which serve as points from which the liquid can flow. The tank effluent flows through the diamond-shaped perforations of the distributors and falls from the ends of the nails in a series of drops.

(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.

Daily except Sundays. Samples were analysed both shaken and settled.

(9) Give (*a*) effluent from the filters; the average of the analyses of the final

—	Four Hours Oxygen absorption.	Three Minutes Oxygen absorption.		Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
		Before Incubation.	After Incubation.					
Shaken - -	2·96	1·74	1·67	2·02	·234	·084	·221	15·7
Settled - -	2·43	1·43	1·26	1·97	·195	—	—	—

Percentage of samples putrescent 50·7 shaken.
Percentage of samples putrescent 23·4 settled.

(*b*) the best analysis and date when sample was taken; and

(*c*) the worst analysis and date when sample was taken

It is a matter of some difficulty to say exactly which is the best and which is the worst analysis, as the different factors vary.

(*b*) Best Analysis. Sample taken 8th October, 1900.

—	Four Hours Oxygen absorption.	Three Minutes Oxygen absorption.		Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Nitrous Nitrogen.	Nitric Nitrogen.	Chlorine.
		Before Incubation.	After Incubation.					
Shaken - -	2·66	1·17	·91	1·58	·188	·223	·164	13·4
Settled - -	1·54	·77	·40	1·58	·117	—	—	—

(*c*) Worst Analysis. Sample taken 24th November, 1900.

Shaken - -	5·03	3·17	3·48	2·53	·33	Nil.	·06	18·6
Settled - -	4·88	2·91	3·28	2·47	·32	—	—	—

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;

16·86 parts per 100,000.
The above number is the average of almost daily analyses of the tank effluent from 28th September to 26th December, 1900.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?

In the earlier stages of the experiment the amount of suspended matter contained in the filtrate was excessive. Latterly it has been about 6 grains per gallon. In many cases the suspended matter was putrescible.

(10) Give a typical analysis of the crude sewage to which the experiment relates.

The following is the average of daily analyses of raw sewage for the quarter ending 26th December, 1900:—

Four hours oxygen absorption - -	11·46
Three minutes oxygen absorption - -	5·47
Ammoniacal nitrogen - - - -	2·01
Albuminoid nitrogen - - - -	0·61
Chlorine - - - - - - -	16·6

(11) Between what dates was the experiment conducted?

From 8th August to 26th December, 1900

If there were any periods of rest state their duration

Occasionally on Sundays.

(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths.

(13) Was any nuisance caused by the experimental works?	No.
(14) Is the experiment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Certainly.
(15) Give particulars of any other observations of importance which have been recorded.	One of the first things met with in connection with this filter is the difficulty experienced in getting the distributing shoots properly level, in order to ensure equal distribution. Any difference of level is of course more noticeable when the flow is small; with an increased flow it is scarcely noticed. After the filter had been working some time it was found that at the junction of the distributing channel with the shoots a considerable amount of leakage took place; this was found to be due in some degree to the partial disintegration of the felt used in making the joint. A considerable amount of sludge accumulates in the distributing channel and shoots, in a comparatively short space of time, which has to be periodically removed in order to ensure the better working of the filter. At the commencement of working a very large amount of suspended matter came away from the filter consisting largely of fine cinder, etc. This amount on further working decreased, but the filtrate always contains a fair amount of suspended matter; further settlement or rough filtration is thus necessitated. During the latter period of working, a quantity of partially disintegrated worms came away in the filtrate. Up to 27th December, the base of the filter was surrounded by earth to a depth of from one to two feet; on this date this earth was removed in order to see whether the purity of the filtrate would be affected; no appreciable difference was however found.
(16) What inferences have been drawn rom the experiment	That in order to ensure continuous filtration being successful, a tank effluent must be used containing as small amount of suspended matter as possible. Results have shown that the tank effluent used contained too much suspended matter to be dealt with by continuous filtration without further settlement. That the best results are obtained with a tank effluent possessing a low oxygen absorption value with a high albuminoid ammonia value. It appears as if, in the case of Manchester sewage, the oxidising power of the filter is exercised largely on matters other than sewage, so that nitrification is to that extent impeded.
(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state— (*a*) what would be the estimated capital cost per head of constructing the works of disposal excluding the cost of land and cost of sewers; (*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

GILBERT J. FOWLER.
Signature of officer under whose direction the experiment was cond cted.

Appendix 9C, Form G.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority	Rural District Council of Walsall.
Population of district	11,000. Number of houses connected to section of sewage works experimented with, 554; estimated population, 3,770.
Water supply per head of the population	Estimated at 10 gallons per day. Supplied by South Staffordshire Waterworks Co. Rain water is stored and used largely for domestic purposes.
Measured dry weather flow of sewage	Average 50,356 gallons per day.
Is any trade refuse taken into the sewers?	The sewage is purely domestic and there are very few water closets.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse?	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Yes, except from back yards.
Officer under whom the experiment has been conducted.	Frederick W. Mager, engineer and surveyor to the Council.
Name and qualification of chemist who has made the analyses.	George Reid, M.D., County Med. Off. of Health, Stafford.
(1) (a) What is the capacity in gallons of the open septic tank or tanks?	68,750 gallons.
(b) If there was more than one tank state whether they were worked in series or in parallel.	Two tanks worked in parallel.
(2) Were any observations made as to the filling up of septic tanks by deposit of sludge? If the sludge was removed from the septic tanks state how often this was done and, approximately what quantity of sludge was removed on each occasion.	Yes, there is at present date (21st March) a deposit of sludge 2 feet deep, equal to 164 cubic yards, but this resulted from the use of precipitants, the sludge so produced not being removed when the tanks were started to be worked as open septic tanks. There has been no appreciable increase of sludge since October, 1900. No sludge has been removed since 21st May, 1900.
(3) (a) What are the form, the area and depth of the filters?	Rectangular, 125 sq. yards in area, 4 ft. 4½ in. deep.
(b) State the nature and size of the filtering material?	Screened and washed coal, top layer 2 ft. 6 in. thick, to pass ⅛ in. screen; 2nd layer, 1 in. thick, to pass ¼ in screen, and retained in ⅛ in. screen, remainder small cobbles.
(c) Were the sides of the filters open or closed?	Closed. Brick walls and cement concrete floor.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	140 gallons. This quantity is governed by the hydraulic capacity of the distributors (*see* 7).
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	No chokage has occurred, and the filtering material is perfectly clean and free from odour.
(5) What was the average quantity of sewage in gallons dealt with daily?	18,000 gallons. The filters are worked 10 hours per day only; the remainder of the tank effluent is treated on prepared land.
(6) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Not as regards the filters.
(7) State by what method the tank liquor was distributed on the filters.	Plan and section are given. AA is a 3 in. cast iron pipe B.B. are 1¼ inch galvanised perforated tubes. The ends of the pipes are stoppered and there is a head of 12 in. from the open septic tanks. The sewage is by these means sprayed over the surface of the beds. I should not recommend this method in a very large installation as the labour necessary to keep the perforations clear would be considerable.

Appendix 9C.

(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.

Samples collected periodically. Samples of sewage, tank effluent, filter effluent, and mixed filter and land effluent on five occasions (excepting sewage 4 occasions) between May 1900 and February 1901. Analysed without filtration or subsidence.

(9) Give (*a*) the average of the analyses of the final effluent from the filters.

	After ordinary tank subsidence.	After septic tank treatment.
Ammoniacal nitrogen -	0·271	0·254
Albuminoid nitrogen -	0·040	0·044
Nitric nitrogen - -	1·320	1·000

(*b*) The best analysis and date when sample was taken, and

May 19th, 1900.

(*c*) The worst analysis and date when sample was taken.

February 4th, 1901.

	B	C.
Ammoniacal nitrogen - - -	0·297	0·252
Albuminoid nitrogen - - -	0·036	0·054
Nitric nitrogen - - - -	1·040	1·000

(*d*) The average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters.

Solids in suspension = 5·3.

(*e*) The average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?

Solids in suspension = 1·08.

(10) Give a typical analysis of the crude sewage to which the experiment relates.

Solids in solution - - - - -	81·2
„ „ suspension - - - - -	44·4
Total - - -	125·6
Chlorine - - - - - - -	8·1
Ammoniacal nitrogen - - -	1·639
Albuminoid nitrogen - - - -	0·999
Oxygen absorbed in 4 hours at 80° F. -	4·629
Nitric nitrogen - - - - -	0·00

(11) Between what dates was the experiment conducted?

If there were any periods of rest, state their duration.

The experiment was commenced on 11th October last and has been carried on continuously to the present date.

(12) Give particulars of any observations which have been made of the temperatures of the filters at different depths.

(13) Was any nuisance caused by the experimental works?

Practically no odour whatever has been observed since septic action became well established.

(14) Is the experiment still proceeding? - - - -

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so?

(15) Give particulars of any other observations of importance which have been recorded.

The sewage generally from the works is passed over prepared land and the effluent is mixed with that from the experimental filters in the outfall pipe. An analysis of this combined effluent is given below, and on comparison with that of the experimental filters it will be seen that the quality of the land effluent is much below that of the filtrate.

Ammoniacal nitrogen - - - -	·231
Albuminoid nitrogen - - - -	·107
Nitric nitrogen - - - - -	·872

(16) What inferences have been drawn from the experiment?

The experiment was commenced to ascertain whether chemical mixing apparatus and sludge pumping machinery, which would otherwise have had to be put down, might be dispensed with. The results both chemically and financially are such as justify the continuance of the works upon the foregoing lines.

(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) What would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.

At present price of materials and labour the cost per head would be 8*s*. to 10*s*.

(*b*) What would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

2*d*. per head.

Note.– It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

FREDK W. MAGER, Engineer and Surveyor, Walsall Rural District Council.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form G.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority	Corporation of York.
Population of district	About 75,000.
Water supply per head of the population	33 gallons per day.
Estimated or measured dry weather flow of sewage	45 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Trade refuse so slight as to be negligible.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Storm water partially when it exceeds the capacity of the sewers or the power of the pumps, the latter being 6,000 gallons per minute. Soil and surface water, no.
Officer under whom the experiment has been conducted	City Engineer and Surveyor.
Name and qualification of chemist who has made the analyses.	(*a*) Thomas Fairley, F.I.C., F.R.S. Edin.; F.C.S. London, &c., &c. (*b*) Edmund Moody Smith, M.D., C.M. Edin.; D.P.H. Camb.; Medical Officer of Health, York.

(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	250,000.
(*b*) If there was more than one tank state whether they were worked in series or in parallel.	One tank only.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	It is tested from time to time by a glass tube, but only a very slight deposit of about 2 inches has been found.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	The supernatent water was drawn off on August 26th after 63 days' use, when the sludge was found to average 2 inches over the whole area of tank; this was removed. No sludge has been removed since. Three series of perforated pipes were laid in this filter from the circumference to within a few feet of the centre. The "bottom," consisting of 8 rows, was laid on the concrete floor. The second or "middle" series, also of 8 rows, was laid 2 ft. above the floor, the third or "top" series, also of 8 rows, laid at 4 ft. above the floor. The letters *a*, *b* and *c* refer in each case to the position in the filter where the temperature was taken— (*a*) is 3 ft. from the circumference. (*b*) is 13 ft. " " (*c*) is 29½ ft. " " The figures given in table at (12) are averages. If further temperatures are required they can be furnished, as we have a large number of observations.
(3) (*a*) What are the form, the area and depth of the filters?	Circular; 399 square yards; 6 ft. 9 in.
(*b*) State the nature and size of the filtering material.	From ½ inch to 2½ inches clinker and coke.
(*c*) Were the sides of the filters open or closed?	Open, built of pigeon-hole brickwork.
(4) What was the rate of filtration in gallons per square yard per 24 hours?	Commenced at 210 gallons, maximum 527 gallons (this is the largest quantity we could get to the filter); average over whole period 426 gallons per square yard per 24 hours.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	No. It has never been reduced in consequence of choking, or any other incident of working.
(5) What was the average quantity of sewage in gallons dealt with daily?	About 160,000 gallons.
(6) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(7) State by what method the tank liquor was distributed on the filters.	By perforated tubing revolving under a head of 6 inches.

Appendix 9C.

(8) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.

From July, 1900, to January 11th, 1901, 13 full analyses have been made, and 7 partial analyses to ascertain the free ammonia, albuminoid ammonia, nitrogen as calcium nitrate and oxygen (4 hours) only.

Samples were taken over from 4 to 12 hours, during the day, and allowed to clear before being analysed.

(9) Give (a) the average of the analyses of the final effluent from the filters;

Total solids	71·67
Mineral matter	64·41
Volatile and organic matter	7·06
Free ammonia	·115
Albuminoid ammonia	·072
Nitrogen as calcium nitrate	8·90
Nitrogen as nitrites	trace
Oxygen required to oxidise organic matter in 4 hours	·597
Reaction	alkaline
Chlorine	9·99
Sediment	trace
Containing organic matter	nil
Analysts	Mr. Fairley and Dr. Smith.

The analyses are of samples taken hourly over a period of 12 hours.

(b) the best analysis and date when sample was taken; and

(c) the worst analysis and date when sample was taken;

——	(b) Aug. 17th, 1900.	(c) Oct. 21st, 1900.
Total solids	70·71	79·9
Mineral matter	64·91	72·5
Volatile and organic matter	5·80	not stated
Free ammonia	·026	·30
Albuminoid ammonia	·044	·077
Nitrogen as calcium nitrate	11·14	11·30
do. as nitrites	trace	trace
Oxygen (4 hours)	·443	1·057
Reaction	alkaline	alkaline
*Smell	nil	nil
Chlorine	10·5	5·91
*Sediment	trace	—
*Containing organic matter	—	—
Analyst	Mr. Fairley.	Dr. Smith.

* These terms were introduced in connection with sewage analyses, and have little or no application to the effluent.

(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;

Not ascertained.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?

Under 1 grain. No.

(10) Give a typical analysis of the crude sewage to which the experiment relates.

Total solids	89·04
Mineral matter	73·37
Volatile and organic matter	15·67
Free ammonia	3·92
Albuminoid ammonia	·54
Nitrogen as calcium nitrate	nil
Nitrogen as nitrites	nil
Oxygen required to oxidise organic matter in 4 hours	3·46
Reaction	alkaline
Smell (when cold)	offensive
Chlorine	14·61
Sediment	61·76
Containing organic matter	29·68
Analyst	Mr. Fairley.

(11) Between what dates was the experiment conducted?

July 5th, 1900, to date, and still in operation.

If there were any periods of rest, state their duration.

The periods of rest were necessitated to improve the spreader and to fill up the bed with clinker; the bed commenced work with only 4 ft. of medium and was filled up from time to time as we were able to accumulate material.

6 a.m. July 18th to 5.30 p.m. July 19th; noon Aug. 23rd to 10.30 a.m., Aug. 26th; 11 a.m., Sept. 11th, to 1 p.m., same day; 6 a.m. Oct. 16th to 10.30 a.m. Oct. 19th.

Appendix 9C.

(13) Was any nuisance caused by the experimental works? — No.

(14) Is the experiment still proceeding? - - - - — Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so? — Yes.

(15) Give particulars of any other observations of importance which have been recorded.

No scum has been formed on the surface of the open septic, except that formed from time to time of gas bubbles, and these have disappeared in a day or two.

In fine weather millions of small flies have been observed in the openings of the brick wall surrounding the filter, and numbers of very fine small red and white worms have come away from the filter in the effluent, during and after it has been standing for a few hours.

For some months after the filter was first brought into use a fine black and white ash was deposited in the surrounding channel, but this has latterly almost disappeared.

The absence of scum on the open septic would lead one to conclude that this tank is used as a subsidence tank only, but the absence of any large quantity of sludge on the bed of the tank shows clearly that septic action is taking place in the tank.

On opening down into the filter for a depth of 3 feet on the 1st February, 1901, I found at about 6 inches below the surface large quantities of the worms and flies referred to in the second paragraph.

(16) What inferences have been drawn from the experiment?

That this system is eminently suited for the treatment of our sewage; it gives uniformly excellent results, the effluent is in a high state of nitrification when it leaves the beds, and is discharged into a river not used for drinking purposes below the outlet. The river in the driest year for 25 years and with a rainfall of only 7 inches in the six months previous to the gauging showed a flow of 136 million gallons in 24 hours, while for 268 days of this dry year the flow was 165 million gallons a day or over.

A moveable screen on wheels to revolve around the filter would serve to protect it from very cold high winds which now go to reduce the temperature in the filter at that side from which the wind is blowing, if the filters were placed together in a nest, a wall surrounding the site would be beneficial in cold weather.

(17) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers;	About £25,000 = 6s. 8d. per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	About £400 = 1s. 8d. per head.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

This cannot now be done ; the analyses are given as received. A standard form for sewage analyses is very much needed.

A. Creer.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form H.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION. (COAL FILTER.)

Name of authority	Manchester.
Population of district	500,000.
Water supply per head of the population	gallons per day.
Estimated or measured dry weather flow of sewage	19,500,000 (about) gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived, and approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1: in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc., F.I.C.
Name and qualification of chemist who has made the analyses.	H. D. Bell, A. C. Oddie, Junior assistants.
(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	CaO 6·28, $FeSO_4$ 7 HgO 6·04.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity, 12,375,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What are the form, the area and depth of the filters?	Rectangular, 25 square yards, 3 ft. deep.
(*b*) State the nature and size of the filtering material.	Coal, 6 in. of large lumps at the bottom, 2 ft. 6 in. all sizes up to ½ in. (including dust). August 11th material taken out and dust washed out.
(*c*) Were the sides of the filters open or closed?	Closed.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	960 gallons per square yard, per 24 hours.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Yes, to 196 gallons per square yard per 24 hours.
(9) What was the average quantity of sewage in gallons dealt with daily?	Period I.—August 5–9, and August 11–29, 24,000 gallons per 24 hours. Period II.—August 30 to September 25, 10,300 gallons per 24 hours. Period III.—October 13 to November 17, 4,900 gallons per 24 hours.
(10) Was the quantity of sewage dealt with increased in time of storm?	No.
If so state to what extent, and how the results were affected by such increase.	

Appendix 9C.

(11) State by what method the tank liquor was distributed on the filters.	By means of wooden shoots laid on the surface of the bed.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Daily, except Sundays. Samples were shaken before analysis.
(13) Give (*a*) the average of the analyses of the final effluent from the filters.	

ANALYTICAL RESULTS—Parts per 100,000.

DATE.	Four Hours' Oxygen Absorption.	Incubation Test. Three Minutes Oxygen Absorption.		Ammoniacal Nitrogen.	Albuminoid Nitrogen.	REMARKS.
		Before.	After.			
1897 :						
Period I.						
5–9, 9–29 August - - -	4·06	3·69*	3·93	2·02	·20	No rest between dates mentioned. Filter worked continuously through 24 hours.
Period II.						
30 August to 25 September -	5·46	3·13	3·71	2·71	·247	Filter allowed to rest 12 hours during each night, and on Sundays.
Period III.						
13 October to 17 November -	4·37	2·77	3·20	2·46	·22	Filter allowed to rest 16 hours in 24. Also on Sundays.

* The figures for 3 minutes' oxygen absorption during this period refer to average from August 26th to 29th only.

(*b*) the best analysis and date when sample was taken ; and	
(*c*) the worst analysis and date when sample was taken ;	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters ;	About 5 to 6 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible ?	Fair amount. Yes.
(14) Give a typical analysis of the crude sewage to which the experiment relates.	The following numbers are the average of daily analyses of *Crude Sewage* from August 25th to December 29th, 1897 :— 4 hours' oxygen absorption - - - 10·86 3 minutes' oxygen absorption - - 4·94 Ammoniacal nitrogen - - - - 2·60 Albuminoid nitrogen - - - - ·66 Chlorine - - - - - - - - 15·4
(15) Between what dates was the experiment conducted ?	From August 5th to November 17th, 1897.
If there were any periods of rest, state their duration.	Periods of rest :—August 9th to 11th, during removal of dust by washing ; 12 hours each day from August 30th to September 25th, and on Sundays ; September 25th to October 13th, measurements of capacity, &c. ; 16 hours each day from October 13th to November 17th, and on Sundays.
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	
(17) Was any nuisance caused by the experimental works ?	No.
(18) Is the experiment still proceeding ?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so ?	
(19) Give particulars of any other observations of importance which have been recorded.	On August 11th the material of the bed was removed, and the fine dust washed out. On replacing the washed material, measurement showed that its water-holding capacity had considerably increased from its previous amount. It is probable that the fine material impeded the drainage of the bed.
(20) What inferences have been drawn from the experiment ?	Continuous filtration carried out in the above manner offers no advantage over intermittent treatment either as regards quantity dealt with, or quality of filtrate produced. Mere straining is quite ineffectual as a means of purification.

Appendix 9C.

(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—

(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers;

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

GILBERT J. FOWLER.

Signature of Officer under whose direction the experiment was conducted.

Form H. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION. BALLAST FILTER. (BURNT CLAY.

Name of authority	Manchester.
Population of district	500,000.
Water supply per head of the population	gallons per day.
Estimated or measured dry weather flow of sewage	19,500,000 (about) gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enter the sewers. Storm overflows are provided at certain points which are supposed to come into action at a dilution of 5 to 1; in certain cases, however they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc. (Vict.), F.I.C.
Name and qualification of chemist who has made the analyses.	H. D. Bell, A. C. Oddie, junior assistants.

(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	CaO 6·28; $FeSO_4\,7H_2O$ 6·04.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity 12,375,000.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What are the form, the area and depth of the filter?	Rectangular; 25 square yards; 3 feet deep.
(*b*) State the nature and size of the filtering material	
(*c*) Were the sides of the filter open or closed?	Closed.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	7,680 gallons per square yard per 24 hours.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Yes, to 291 gallons per square yard per 24 hours.
(9) What was the average quantity of sewage in gallons dealt with daily?	Period I.—August 23–29, 192,000 gallons per 24 hours. Period II.—August 30–September 22, 82,300 gallons per 24 hours. Period III.—Sept. 23–25, 192,000 gallons per 24 hours. Period IV.—October 13–November 17, 7,275 gallons per 24 hours.
(10) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(11) State by what method the tank liquor was distributed on the filters.	By means of wooden shoots laid on the surface of the beds.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Daily except Sundays. Samples shaken before analyses.

Appendix 9C. (13) Give (*a*) the average of the analyses of the final effluent from the filters

ANALYTICAL RESULTS.—Parts per 100,000.

DATE.	Four Hours Oxygen Absorption.	Incubator Test. Three Minutes Oxygen Absorption.		Ammoniacal Nitrogen.	Albuminoid Nitrogen.	REMARKS.
		Before.	After.			
1897 :						
Period I.						
23–29 August - - - -	5·23	*3·83	4·53	2·17	·241	Filter kept always full by means of side pipe. Filtration continuous, no rest.
Period II.						
30 August to 22 September -	5·83	3·53	3·76	2·40	·282	Filter allowed to rest for 12 hours during the night, the side pipe being taken off to allow the bed to empty ; also rests on Sundays.
Period III.						
23–25 September - - -	6·79	4·01	4·60	3·00	·282	As in Period II., with the exception that the side pipe was not taken off during the period of rest, consequently the bed alwa remained full.
Period IV.						
13 October to 17 November -	5·51	3·31	3·84	2·34	·282	Filter resting 16 hours in 24. Bed kept full while working and emptied before resting.

* The numbers for 3 minutes oxygen absorption refer to average from 26 to 28 August, 1897.

(*b*) the best analysis and date when sample was taken ; and

(*c*) the worst analysis and date when sample was taken ;

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters ;

About 5 to 6 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible ?

Very fair amount. Yes.

(14) Give a typical analysis of the crude sewage to which the experiment relates.

The following numbers are the average of daily analyses of crude sewage from August 25th to December 29th, 1897 :—

4 hours oxygen absorption - - -	10·86
3 minutes oxygen absorption - - -	4·94
Ammoniacal nitrogen - - - -	2·60
Albuminoid nitrogen - - - -	·66
Chlorine - - - - - - -	15·4

(15) Between what dates was the experiment conducted ?

If there were any periods of rest, state their duration.

August 23rd to November 7th, 1897. 12 hours each day from August 30 to September 25th, and Sundays. September 26th to October 13th for measurements of capacity. 16 hours each day from October 13th to November 17th.

(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.

(17) Was any nuisance caused by the experimental works ?

No.

(18) Is the experiment still proceeding ?

If so, may the Commission inspect the works, should they deem it desirable to do so ?

No.

(19) Give particulars of any other observations of importance which have been recorded.

(20) What inferences have been drawn from the experiment ?

Continuous filtration carried out in the above manner offers no advantage over intermittent treatment. Mere straining is quite ineffectual as a means of purification.

(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers ;

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression " subsidence tanks " is intended to denote tanks which are used so that little or no " septic " action is produced.

GILBERT J. FOWLER.

Form H. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION. (WILSON FILTER.)

Name of authority	Manchester.
Population of district	400,000 to 500,000.
Water supply per head of the population	gallons per day.
Estimated or measured dry weather flow of sewage	gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Yes.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Mostly enters the sewers. Storm overflows are provided at certain points, which are supposed to come into action at a dilution of 5 to 1; in certain cases, however, they fail to answer their purpose.
Officer under whom the experiment has been conducted	Gilbert J. Fowler, M.Sc., F.I.C.
Name and qualification of chemist who has made the analyses.	H. D. Bell, A. C. Oddie, Junior Assistants.
(1) What was the nature of the chemical or chemicals used?	Lime and copperas.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	CaO 6·28, $FeSO_4 7, H_2O$ 6·04.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	
(4) What is the capacity in gallons of the subsidence tanks?	Eleven tanks. Total capacity 12,375,000.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	3,000 tons per week. About once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (a) What are the form, the area and depth of the filters? (b) State the nature and size of the filtering material (c) Were the sides of the filters open or closed?	The filter consisted essentially of a layer of filtering medium about 6 in. thick (either coke, coal or sand), together with a flushing tank by means of which the medium was cleaned from time to time automatically by upward flush. The whole arrangement was constructed in ironwork.
(8) What was the rate of filtration in gallons per square yard per 24 hours? State whether the rate of filtration was reduced during the experiment, in consequence of the choking of the filters, and, if so, to what extent.	
(9) What was the average quantity of sewage in gallons dealt with daily?	84,816 gallons per day. The above includes, to the extent of 7½ per cent., water used for washing purposes.
(10) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	
(11) State by what method the tank liquor was distributed on the filters.	
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Daily except Sundays.

Appendix 9C.

(13) Give (*a*) the average of the analyses of the final effluent from the filters;	
(*b*) the best analysis and date when sample was taken; and	
(*c*) the worst analysis and date when sample was taken;	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;	3·9 parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	Nil.
(14) Give a typical analysis of the crude sewage to which the experiment relates.	
(15) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	December, 1896, to November 3rd, 1897.
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	
(17) Was any nuisance caused by the experimental works?	No.
(18) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(19) Give particulars of any other observations of importance which have been recorded.	In the earlier stages of the working of this filter the removal of suspended and putrescible matters was such as to render the filtrate in many cases non-putrefactive; at each washing, however, some residuum remained, and the filtrate soon ceased to be non-putrefactive. On taking the filter to pieces, a considerable amount of black putrescent matter was found in the filter and in the pipes leading to it.
(20) What inferences have been drawn from the experiment?	That such a filter as this, while having its possible uses as a roughing filter, is not suited for the final purification of sewage. In the removal of silt from river water or suspended matter from trade refuse, it would no doubt find useful application. The composition of the suspended matter removed from the effluent showed that a considerable amount of iron and lime from the treatment was passing away in the tank effluent and that therefore the addition of those chemicals must be limited in amount.
(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

GILBERT J. FOWLER.

Signature of Officer under whose direction the experiment was conducted.

Form H. Appendix 9C.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	Ardsley Urban District Council.
Population of district (Ardsley and Stairfoot area) -	5,250.
Water supply per head of the population - - -	$10\frac{1}{2}$ to 11 gallons per day.
Estimated or measured dry weather flow of sewage -	55,000 gallons per day.
Is any trade refuse taken into the sewers?	No.
If so, state from what processes it is derived, and approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted	The works are permanent, not experimental, and have been managed by a man under the Council's surveyor.
Name and qualification of chemist who has made the analyses.	*A.*—Dr. Wilson, of the West Riding Rivers Board. *B.*—J. Carter Bell, Cheshire County Analyst, &c.

(1) What was the nature of the chemical or chemicals used?	Alumino-ferric.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	No accurate account kept, probably about 10.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Yes, roughly.
(4) What is the capacity in gallons of the subsidence tanks?	50,624.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	No account kept.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What are the form, the area and depth of the filters?	About 200 square yards; four in number; filtering material 2 feet 6 inches deep, walls 18 inches higher.
(*b*) State the nature and size of the filtering material -	Gravel, sand and "polarite."
(*c*) Were the sides of the filters open or closed? -	Closed. Arranged for reversing flow for washing surface
(8) What was the rate of filtration in gallons per square yard per 24 hours?	Capable of any speed up to 800 gallons per yard per 24 hours.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Yes, say to less than 100 gallons per yard. Surface only choked and required washing every few days.
(9) What was the average quantity of sewage in gallons dealt with daily?	Probably 100,000 gallons.
(10) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	In tanks, treated till diluted with storm water 6 times; in filters 3 times dilution.
(11) State by what method the tank liquor was distributed on the filters.	Allowed to flow on to a long channel, level with the surface of material. Each filter allowed some hours rest daily.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	The Council only had one analysis made. The Rivers Board take samples at irregular intervals, the following being one of those supplied by them, being one of many.

Appendix 9C.

(13) Give (*a*) the average of the analyses of the final effluent from the filters.

(*b*) the best analysis and date when sample was taken, and

(*c*) the worst analysis and date when sample was taken;

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?

Dr. Wilson's Report.

5th September, 1899. Filter effluent.

Slightly turbid.
Sediment, very small yellow.
Odour, slightly earthy.
Reaction, neutral.

	parts per 100,000.
Chlorides equal to sodium chloride - -	13·16
Oxygen absorbed in 4 hours at 80° Fahr. -	0·65

(14) Give a typical analysis of the crude sewage to which the experiment relates.

Mr. Bell's Report—Filter effluent.

30th March, 1897.

	Grains per gallon.
Total solids at 212° F. - - - - -	74·0
Mineral solids - - - - - -	59·0
Loss on ignition - - - - -	15·0
Chlorine - - - - - -	4·8
Free ammonia - - - - - -	1·1
Albuminoid ammonia - - - -	·11
Oxygen required for 15 minutes - -	·16
" " 3 hours - -	·30

This is a first class clear effluent and fit to run into any stream or river.

(15) Between what dates was the experiment conducted?

The works have been in continuous operation since June 1896.

If there were any periods of rest, state their duration.

(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.

None made.

(17) Was any nuisance caused by the experimental works?

No nuisance

(18) Is the experiment still proceeding?

If so, may the Commission inspect the works, should they deem it desirable to do so?

The works are in regular operation, and the Commission may visit with or without prior notice.

(19) Give particulars of any other observations of importance which have been recorded.

Although the works give the Rivers Board general satisfaction, the Local Government Board have required the District Council to run the effluent over the available land, this land; is about to be prepared for the purpose.

(20) What inferences have been drawn from the experiment?

It is possible that in the near future the works will be converted into an efficient bacteria system, a method for which the construction of tanks and filters could easily be adapted, the object being to save expense of chemicals and reduce quantity of sludge.

(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—

(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.

The actual total cost of outfall works was about £2,300.

(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

No reliable data available.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

Theo. S. McCallum, A.M.Inst.C.E.
Engineer for the Works.

Signature of Officer under whose direction the experiment was conducted.

20th February, 1901

Appendix 9C

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	Birkenshaw Urban District Council.
Population of district - - - - - - - -	About 2,500.
Water supply per head of the population - - -	About nine gallons per day.
Estimated or measured dry weather flow of sewage -	Estimated at 107,460 gallons per day.
Is any trade refuse taken into the sewers? - - -	No.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted.	The Surveyor of the Council.
Name and qualification of chemist who has made the analyses.	The inspectors of the West Riding of Yorkshire Rivers Board, and the officers of that Board.
(1) What was the nature of the chemical or chemicals used?	Alumino-ferric.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	One cake per day, or about 12 tons per annum.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	The chemicals were decreased when there was a large flow of storm water.
(4) What is the capacity in gallons of the subsidence tanks?	383,465.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	About five tons once a week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(7) (*a*) What are the form, the area and depth of the filters?	No. 1 filter bed, 50 feet × 40 × 4 feet 6 inches deep. No. 2 filter bed, 36 feet × 25 × 5 feet deep.
(*b*) State the nature and size of the filtering material	One foot of broken stone, $1\frac{1}{4}$ foot broken clinker, 1 foot of breeze, 1 foot small stone, and 6 inches sand.
(*c*) Were the sides of the filters open or closed?	Open.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	
9) What was the average quantity of sewage in gallons dealt with daily?	
(10) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	In some cases from 2 to 3 tons of grit come down into outfall works, but not into the tanks.
(11) State by what method the tank liquor was distributed on the filters.	From wood floating arm into 6 inches iron pipe with valve.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	No analyst employed by the Council. The Rivers Board before-mentioned could answer this and following queries up to and inclusive of No. 16.
(13) Give (*a*) the average of the analyses of the final effluent from the filters.	
(*b*) the best analysis and date when sample was taken, and	
(*c*) the worst analysis and date when sample was taken,	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters.	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	

Appendix 9C.

(14) Give a typical analysis of the crude sewage to which the experiment relates.	
(15) Between what dates was the experiment conducted?	
If there were any periods of rest, state their duration.	
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	
(17) Was any nuisance caused by the experimental works?	No.
(18) Is the experiment still proceeding?	
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes, with pleasure
(19) Give particulars of any other observations of importance which have been recorded.	
(20) What inferences have been drawn from the experiment?	The works are satisfactory
(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

EDWIN WALTER SMITH (Surveyor),
Signature of Officer under whose direction
the experiment was conducted.

Form H.

Appendix 9C

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CONTINUOUS FILTRATION, AFTER CHEMICAL PRECIPITATION.

Name of authority	Buxton.
Population of district	Season 20,000 ; resident 10,000.
Water supply per head of the population	About 50 gallons per day.
Estimated or measured dry weather flow of sewage	One million gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse?	No.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted	Wm. Hedley Grieves, Town Surveyor.
Name and qualification of chemist who has made the analyses.	Mr. R. Wright, F.C.S., Examiner to the Pharmaceutical Society of Great Britain, chemist, Buxton, also Dr. Barwise, County Medical Officer of Health, Derby, and Dr. J. C. Thresh, County Medical Officer of Health, Chelmsford.

(1) (*a*) What are the form, the area and depth of the filters?

(*a*)

Description.	Dimensions.	Area.	Depth.
	ft. ins. ft. ins.	sq. ft.	ft. ins.
Coke breeze	19 0 by 6 5	126	3 1
Destructor breeze	19 7 ,, 9 1	180	3 1
Coal filter	19 0 ,, 6 2	115	4 0

(*b*) State the nature and size of the filtering material

(*b*)
Coke Breeze :—In the bottom 4-inch land drain tiles are laid, herring bone fashion, covered with—

- 2-inch layer of 2-inch limestone.
- 2-foot ,, screened coke breeze.
- 2-inch ,, 2-inch limestone.
- 1-inch ,, limestone chippings, ¼ inch.
- 4-inch ,, screened coke breeze.

Destructor Breeze Filter :—4-inch land drain tiles as above, covered with—

- 2-inch layer of 2-inch limestone.
- 2-foot ,, screened destructor breeze.
- 2-inch ,, 2-inch limestone.
- 1-inch ,, limestone chippings.
- 4-inch ,, screened destructor breeze.

Coal Filter :—Land drain tiles as above, covered with—

- 3-inch layer of coal to pass ½-inch mesh.
- 1-inch ,, ,, stop at $\frac{3}{16}$-inch mesh.
- 2-inch ,, ,, ,, ⅜-inch mesh.
- 2-foot screened destructor breeze.
- 5-inch layer of coal to pass ¼-inch mesh.
- 6-inch ,, ,, ,, ⅛-inch mesh.
- 4-inch clean sharp sand.

(*c*) Were the sides of the filters open or closed? — Closed.

(2) What was the rate of filtration in gallons per square yard per 24 hours?

	Maximum.	Minimum.
Coal	1,032	780
Destructor	2,000	719
Coke	1,347	500

State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.

In the case of the coal filter the rate of filtration was reduced by choking, but I think this is probably due to the very fine mesh of the coal, in the other filters choking did not appear to take place to any very great extent.

(3) What was the average quantity of sewage in gallons dealt with daily?

About 30,000 gallons.
N.B.—The filters were only working for 12 hours daily.

(4) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.

On the filters, no ; practically the same flow, regulated by gauges.

Appendix 9C.

(5) State by what method the tank liquor was distributed on the filters.

A portion of the precipitation tank effluent is conveyed direct to the filters by means of a wooden trough, 40 feet long, into a feed channel 11 feet long, from which there are three outlets on to the respective filters, each controlled by a sluice and fitted with a gauge. There is a layer of clean sharp sand on the top of the filtering material which is regularly raked and which ensures the even distribution of the effluent over the surface of the filters.

(6) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.

	No. of Analyses.		No. of Analyses.
January 1897 -	1	December 1897 -	2
February 1897 -	2	October 1898 -	1
March 1897 -	3	November 1898 -	1
April 1897 -	1	December 1898 -	1
June 1897 - -	1	March 1899 -	1
October 1897 -	1		

(7) Give (*a*) the average of the analyses of the final effluent from the filters.

Quantities stated in parts per 100,000.

	Oxygen Absorbed.	Free and Saline Ammonia.	Alluminoid Ammonia.	Nitrogen as Nitrates.
Average of Mr. Wright's analyses:				
Destructor filter - - - - -	1·2943	·3995	·070757	—
Coke filter - - - - - -	·838	·4677	·07064	—
Coal filter (one analysis only) -	·26	·60	·0670	—
Average of Dr. Barwise's analyses:				
Destructor filter - - - - -	—	·41	·0604	·32
Coke filter - - - - - -	—	·39	·0576	·3366
Coal filter - - - - - -	---	·56	·039	·566

(*b*) the best analysis and date when sample was taken, and

·02 parts per 100,000 of albuminoid ammonia from the coal filter on 16th November 1898.

(*c*) the worst analysis and date when sample was taken.

·157 parts per 100,000 of albuminoid ammonia from the destructor filter on 5th December 1897.

(*d*) One estimation made of the solids in suspension in the tank liquor as it went on to the filters.

Dr. Thresh's analysis. Raw sewage, 27·6 grains per gallon. Tank effluent, 5·3 grains per gallon (one analysis only).

(*e*) One estimation made of the solids in suspension in the final effluent. Were these solids putrescible?

Dr. Thresh's analysis. 3·0 grains per gallon not putrescible from the coke filter.

(8) Give a typical analysis of the crude sewage to which the experiment relates.

Quantities in parts per 100,000. Chlorine, 2·1. Free and saline ammonia, 1·05. Albuminoid ammonia, ·291.

(9) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.

January 1897 to present date. The filters have only worked 12 hours per day, resting during the night. When the filtrate has shown signs that the purification was not going on satisfactorily, the filters have been allowed to rest for periods ranging from a week to a month at a time.

(10) Give particulars of any observations which have been made of the temperatures of the filters at different depths.

(*See* answer to No. 13.)

(11) Was any nuisance caused by the experimental works?

None whatever.

(12) Is the experiment still proceeding?

Yes.

If so, may the Commission inspect the works, should they deem it desirable to do so.

Yes, certainly.

(13) Give particulars of any other observations of importance which have been recorded.

After four years' working the filtering medium has not required renewing in any filter. The filters are not materially affected by cold weather and even when frozen during the night's rest the temperature of the sewage is such that in a short time the filters work as though they had never been frozen. The Council are so satisfied with the result of the experiments that they have decided to construct filter beds to deal with the whole of the tank effluent, and for that purpose have secured three acres of land three-quarters of a mile below the present works, and plans are now being prepared for the same. The Local Government Board have sanctioned the borrowing of the money for the land

(14) What inferences have been drawn from the experiment?	1st. Continuously working the filters day and night causes them to become clogged and also causes a falling off of purification in the analytical results. 2nd. By working the filters intermittently, *i.e.*, by working during the day and resting during the night, with an occasional week's rest, say every three months, the result is a much more regular and a clearer effluent. 3rd. Owing to the fact that Buxton sewage is very weak, I have no hesitation in saying that 500 gallons per day can be safely treated per square yard of filter.
(15) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—	Approximate estimate for filters, 6,000*l*.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	£5 per head of population, including pipe line from present works, but exclusive of site. *Note.*—Population taken as 12,000, which includes Fairfiels Urban district, whose sewage we treat.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	About 1*s*. per head.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

W. H. Grieves,
Signature of Officer under whose direction
the experiment was conducted.

Appendix 9C. Form H.

THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority	Borough of Chorley.
Population of district	26,000.
Water supply per head of the population	19¼ gallons per day
Estimated or measured dry weather flow of sewage	600,000 to 700,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse:	Very little. From three breweries and one tannery. Blood from abattoirs. Cannot tell percentage.
Is the storm, soil or surface water, wholly or partially excluded from the ordinary sewers?	No.
Officer under whom the treatment has been conducted	Alderman H. F. Hibbert, J.P., C.C.
Name and qualification of chemist who has made the analyses	W. Naylor, F.I.C., F.C.S., Chief Inspector of the Ribble Watershed Committee.

(1) What was the nature of the chemical or chemicals used?	Ferrozone, ferral, and alumino-ferric.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	8·31.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	They vary every day, the highest being 11·2, the lowest 6·56.
(4) What is the capacity in gallons of the subsidence tanks?	1,442,800.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	526 tons per week of sludge containing 90 per cent. of water. The sludge was removed after every second filling.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(7) (*a*) What are the form, the area and depth of the filters?	Rectangular; 1,388 superficial yards; 3 feet 3 inches deep.
(*b*) State the nature and size of the filtering material.	Top layer is sand from Fleetwood Harbour, then 12 inches of polarite and sand mixed, pea and bean gravel, and then graded from two to three inches boulder stones.
(*c*) Were the sides of the filters open or closed?	Closed.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	450 gallons.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	The above filters are washed weekly, and filter more rapidly the first day after washing than the following days.
(9) What was the average quantity of sewage in gallons dealt with daily?	About 700,000.
(10) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	The daily flow increased in case of storms, three to four times the normal flow. In such a case as much as would go through the works would be treated. The remainder would go into the river untreated.
(11) State by what method the tank liquor was distributed on the filters.	By means of syphons. The syphons unseal every 40 minutes, day and night, and cover the filters about three inches deep. The capacity of the syphon chamber is 2,500 gallons; this quantity of water is therefore sent through the filters every 40 minutes. There is thus a layer of air between each filtration or passage of the water through the filters, which undoubtedly purifies the interior strata of the filters.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Samples examined as drawn, after shaking bottles.

Appendix 9C.

(13) Give (*a*) the average of the analyses of the final effluent from the filters;	·058 albuminoid nitrogen.
(*b*) the best analysis and date when sample was taken; and	·022 November, 1900.
(*c*) the worst analysis and date when sample was taken;	·088 February, 1900. The excessive impurity in this sample (*c*) was found to have been caused by a leakage in the pipe conveying the sand wash water from the filters to the sand wash water tank.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;	Two to three parts per 100,000.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	Nil.
(14) Give an average analysis of the crude sewage to which the treatment relates.	Per 100,000. Albuminoid nitrogen - - - - ·66 Dissolved solids, about - - - 80·00 Suspended solids, from - - - 10·00 to 25·00 Chlorine - - - - - - - 9·00 The crude sewage is constantly varying owing to the conversion from pail to water carriage system which is now going on. This variation is caused by the emptying of the pails into the sewer. I have known the crude sewage to contain 5·0 per 100,000 albuminoid nitrogen.
(15) Between what dates was the treatment conducted? If there were any periods of rest state their duration.	From October 1895 to date.
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	Have not made any.
(17) Was any nuisance caused by the treatment works?	No.
(18) Is the treatment still proceeding?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	The Commission have inspected the works.
(19) Give particulars of any other observations of importance which have been recorded.	I have experimented with continuous and quiescent flow on precipitation tanks, and have come to the conclusion that it is impossible, with continuous flow, to get as good results as from quiescent flow, either in quantity of water treated, or quality of the final effluent, if the said effluent has to be filtered through any filter which has a top stratum of sand. I have also made exhaustive experiments on continuous and intermittent flow on filters composed of sand, polarite, and gravel, the results of which prove that a water-logged filter will not produce satisfactory results, either in point of quantity or quality. I have also experimented with coke filters, on the same lines as the above, with the same results.
(20) What inferences have been drawn from the treatment?	I have visited all the principal sewage works in Lancashire, and am conversant with the different methods there in operation for the treatment of sewage, and as a result believe it is possible to treat sewage effectively by other systems than the one in operation at Chorley. I think, however, that none of them can produce an effluent as good as Chorley, in point of quantity, and quality of gallons treated, for the same expenditure, capital and current, in consequence of the greatly increased area of the filters.
(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state—	This system has been in operation since October 1895.
(*a*) what is the actual capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	The works have cost 14*s.* 7*d.* per head of the population (26,000) (£19,000).
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	Annual expenditure £1,373 9*s.* = 1*s.* 0½*d.* per head; but including the payment of interest and sinking fund the total charge per head of the population is 1*s.* 9¾*d.*

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

HENRY F. HIBBERT.

Signature of Officer under whose direction the treatment was conducted.

Appendix 9C.

Form H.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	Littleborough.
Population of district - - - - - - -	10,878 (1891).
Water supply per head of the population - - -	15 gallons per day.
Estimated or measured dry weather flow of sewage- -	160,000 to 200,000 gallons per day.
Is any trade refuse taken into the sewers? - - - - If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	From one works only, known as flannelette finishing, about 7,000 gallons per day.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially excluded.
Officer under whom the experiment has been conducted.	No experiments as such.
Name and qualification of chemist who has made the analyses.	
(1) What was the nature of the chemical or chemicals used?	Alumino-ferric.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	Five grains per gallon.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	The same ratio.
(4) What is the capacity in gallons of the subsidence tanks?	320,000.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	Pressed sludge for 1900, 516 tons, containing about 55 per cent. of moisture.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent generally; may be and are occasionally used continuous.
(7) (a) What are the form, the area, and depth of the filters?	300 square yards area; square; and 2 ft. 6 in. deep.
(b) State the nature and size of the filtering material.	6 in. broken stone, size 2 in., in the bottom, then 6 in. of clinkers, 8 in. of cinders, size 1 in. to 1½ in., and 10 in. of fine cinders or engine ashes.
(c) Were the sides of the filters open or closed? -	Closed (filters ventilated).
(8) What was the rate of filtration in gallons per square yard per 24 hours?	800 to 900 gallons per square yard.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent?	Work regularly for some 7 years.
(9) What was the average quantity of sewage in gallons dealt with daily?	About 180,000.
(10) Was the quantity of sewage dealt with increased in time of storm?	Yes, more than double occasionally.
If so, state to what extent, and how the results were affected by such increase.	
(11) State by what method the tank liquor was distributed on the filters.	Floating arms from tanks and over wood troughs on to the filters.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Analysis left to Mersey and Irwell Committee.

Appendix 9C.

(13) Give (*a*) the average of the analyses of the final effluent from the filters :	23 samples. Oxidizable organic matter—oxygen absorbed, 4 hours : grains per gallon, 0·287.
(*b*) the best analysis and date when sample was taken ; and	January 29th, 1896, 0·07.
(*c*) the worst analysis and date when sample was taken ;	September 27th, 1899, 1·03, next worst July 23rd, 1900 0·57.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters ;	No observations.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible ?	No observations.
(14) Give a typical analysis of the crude sewage to which the experiment relates.	No observations.
(15) Between what dates was the experiment conducted? If there were any periods of rest, state their duration.	o experiments.
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	No experiments.
(17) Was any nuisance caused by the experimental works ?	No experiments.
(18) Is the experiment still proceeding ? If so, may the Commission inspect the works, should they deem it desirable to do so ?	No experiments.
(19) Give particulars of any other observations of importance which have been recorded.	
(20) What inferences have been drawn from the experiment ?	
(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers ;	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

George H. Wild
Signature of Officer under whose direction the works are conducted.

Appendix C9. Form H.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority	Normanton Urban District Council.
Population of district	Last census, 10,234. Estimated to March 1899, 13,310.
Water supply per head of the population	13 gallons per day. Total 175,000 gallons per day.
Estimated or measured dry weather flow of sewage	Estimated 135,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	No.
Officer under whom the experiment has been conducted	No experiment made beyond the ordinary daily process of treating the sewage.
Name and qualification of chemist who has made the analyses.	None made by Council, but Rivers Board have done so. Council are not aware of results of analysis.
(1) What was the nature of the chemical or chemicals used?	Alumino-ferric is used as a precipitant at the sewage works.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	No analysis made by Council, but 14 cwts. of alumino-ferric are used weekly in the sewage treatment.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	*See* answer to No. 2.
(4) What is the capacity in gallons of the subsidence tanks?	75,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	18,000 gallons. Weekly.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What are the form, the area and depth of the filters?	Square ; 160 sq. yds. ; 3 ft. 3 in
(*b*) State the nature and size of the filtering material.	12 inches of gravel, from 2 inches to pea size. 12 inches of polarite and sand, and 15 inches of sand.
(*c*) Were the sides of the filters open or closed?	Closed.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	Quantity not measured.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	Care is taken that the filters do not choke.
(9) What was the average quantity of sewage in gallons dealt with daily?	135,000 gallons.
(10) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Naturally it increases, but to what extent I cannot say.
(11) State by what method the tank liquor was distributed on the filters.	By gravitation in open channels.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	No analysis made by Council, but by Rivers Board. Council have no results.
(13) Give (*a*) the average of the analyses of the final effluent from the filters.	*See* answer to No. 12.
(*b*) the best analysis and date when sample was taken, and	
(*c*) the worst analysis and date when sample was taken,	*See* answer to No. 12.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters.	*See* answer to No. 12.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	*See* answer to No. 12.
(14) Give a typical analysis of the crude sewage to which the experiment relates.	*See* answer to No. 12.
(15) Between what dates was the experiment conducted?	
If there were any periods of rest, state their duration.	*See* answer to No. 12.
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	No observations made.
(17) Was any nuisance caused by the experimental works?	No complaint has been made to the Council, and the Rivers Board seem satisfied.
(18) Is the experiment still proceeding?	The Commissioners may inspect the sewage works at any time on giving reasonable notice.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(19) Give particulars of any other observations of importance which have been recorded.	None.
(20) What inferences have been drawn from the experiment?	The effluent appears to be satisfactory.
(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	The system has been adopted, and is at present satisfactory to the West Riding Rivers Board.
(a) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	
(b) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

J. Eaton,
Sanitary Inspector.

Appendix 9C.

Form H.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority	Royton Urban District Council.
Population of district	15,600 (present estimated).
Water supply per head of the population	
Estimated or measured dry weather flow of sewage	About 400,000 gallons per day.
Is any trade refuse taken into the sewers? If so, state from what process it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Only partially excluded.
Officer under whom the experiment has been conducted	Manager of the sewage works, Mr. David Wolstencroft.
Name and qualification of chemist who has made the analyses.	Wm. Naylor, Chief Inspector to the River Ribble Joint Committee. Also by Frank Scudder, F.I.C., for Sir Henry Roscoe.
(1) What was the nature of the chemical or chemicals used?	When experiments were made "Ferozone" was the precipitant used. For several years however alumino-ferric has been used, and it is considered more satisfactory and less variable in quality.
(2) What was the normal proportion of chemical or chemicals (in grains per gallon) used?	5·90 grains per gallon (average for a year).
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Yes, we have an automatic mixer whereby the amount of precipitant used varies according to the flow of sewage.
(4) What is the capacity in gallons of the subsidence tanks?	6 tanks, 90,000 gallons each, or a total of 540,000 gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	36·65 tons of compressed sludge cake (weight after compression) removed from tanks into sludge pit every alternate day ready for being pumped into presses.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(7) (*a*) What are the form, and area and depth of the filters?	20 yards × 5 yards each and 3 ft. deep. We have 8 filters ∴ total superficial area = 800 superficial yards.
(*b*) State the nature and size of the filtering material	The "International" Polarite Filter, viz., 9 in. sand; 9 in. polarite and sand, mixed in proportion 6 in. polarite to 3 in. sand; 2 in. fine sand; 3 in. pea gravel; 6 in. walnut size gravel; 7 in. bolder size.
(*c*) Were the sides of the filters open or closed?	Sides are closed, but 3 in. ventilating pipes are built in every two feet.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	During an experiment lasting 2 hours and 6 minutes, effluent was filtered at a rate of 2,688 gallons per superficial yard per 24 hours.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	No.
(9) What was the average quantity of sewage in gallons dealt with daily?	425,000 gallons (average daily flow for last 12 months).
(10) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Yes. The normal flow would sometimes be trebled. Improved purification on account of greater dilution.
(11) State by what method the tank liquor was distributed on the filters.	By centre and side distributing channels above the surface of the filters.

Appendix 9C

(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Samples are taken frequently but at irregular intervals and at surprise visits paid by the inspectors of the Mersey and Irwell Joint Committee. They are afterwards analysed by or on behalf of Sir H. E. Roscoe, the analyst for the Joint Committee.
(13) Give (*a*) the average of the analyses of the final effluent from the filters;	Oxidisable organic matter. Oxygen absorbed 4 hours test, K_2MnO_4 solution. Average of the 10 last reports received from analyst to Mersey and Irwell Joint Committee ·49 grains per gallon.
(*b*) the best analysis and date when sample was taken; and	·13 grain per gallon. 4th December, 1895.
(*c*) the worst analysis and date when sample was taken;	1·36 grains per gallon. 15th July, 1898.
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters;	Cannot say.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	Not been estimated.
(14) Give a typical analysis of the crude sewage to which the experiment relates.	In parts per 100,000.

Date.	Free. Ammonia.	Albuminoid Ammonia.	Oxygen absorbed in 4 hours.	Albuminoid Ammonia percentage of Purification.
1897				
27 April -	2·108	·384	3·5	80·2
29 April -	2·598	·602	1·7	80·9
4 May -	4·284	·818	7·3	91·7

(15) Between what dates was the experiment conducted? If there were any periods of rest state their duration.	The above experiments were made from April to May 1897. We have not had experiments carried out since. (*See* enclosed report.)
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	Nil.
(17) Was any nuisance caused by the experimental works?	No.
(18) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes, certainly.
(19) Give particulars of any other observations of importance which have been recorded.	Nil.
(20) What inferences have been drawn from the experiment?	The works have been in operation since 1894 and continue to give successful results.
(21) If it is considered that it would be practicable to adopt this system for the whole of the sewage of the district, please state	It is adopted for the whole district.
(*a*) What would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	Difficult to give, as the sewage works comprise tanks and filters, filtration plots, sewage-pressing machinery, refuse destructors.
(*b*) What would be the estimated annual cost per head, of purifying the sewage by this system, excluding the annual repayment of any loan.	About 1*s.* 5*d.* per head per annum.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

THOS. BLEASDALE,
Clerk and Surveyer to Council.
Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

Form H.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority	Walsall.
Population of district	Estimated 85,000.
Water supply per head of the population	35 gallons per day.
Estimated or measured dry weather flow of sewage	3,000,000 gallons per day.
Is any trade refuse taken into the sewers?	Yes.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	Curriers' tan pits, &c. Acids used in cleaning hardware goods.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	The Corporation have a surface water scheme in progress, part of which is laid—£3,000 out of £25,000.
Officer under whom the experiment has been conducted.	Borough Surveyor.
Name and qualification of chemist who has made the analyses.	E. W. T. Jones, F.I.C., borough analyst.
(1) What was the nature of the chemical or chemicals used?	Ferrous sulphate and lime.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	15 grains of iron.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give particulars of any such variations.	Chemicals are varied according to the sewage; at times no iron is required.
(4) What is the capacity in gallons of the subsidence tanks?	Two precipitation tanks each of about half a million gallons.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	Average (every ten days removal) amounting to 890 cubic yards or 623 cubic yards per week.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(7) (*a*) What are the form, the area and depth of the filters?	Two filters 87 ft. 0 in. × 27 ft. 0 in. × 2 ft. 8 in. deep.
(*b*) State the nature and size of the filtering material.	Polarite and sand with fine and coarse stone beneath.
(*c*) Were the sides of the filters open or closed?	Six ventilators in each bed; they go into body of filter.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	400 gallons.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	If the surface is not cleaned the filters soon choke, and 1 inch of sand has then to taken off and replaced with clean. The rate of flow, if not kept clean, will be reduced quite one-half.
(9) What was the average quantity of sewage in gallons dealt with daily?	Only two experimental filters down, and for the best results 400 gallons per square yard of filter should not be exceeded per 24 hours.
(10) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	No.
(11) State by what method the tank liquor was distributed on the filters.	One central distributing trough full length of filter.
(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	From January 9th 1897 to April 26th 1895. 13 samples analysed. Shaken before being analysed.
(13) Give (*a*) the average of the analyses of the final effluent from the filters;	Grains per gallon. Total solid matter - 64·57 Free ammonia - ·734 Organic ammonia - ·041 Nitrates - ·87 Chlorine - 6·56 Oxygen absorbed 80 - ·347

Appendix 9C.

Question	Answer
(b) the best analysis and date when sample was taken; and	20th February 1897: Solids 68·60; Free NH_3 ·434; Alb. NH_3 ·024; Nitrates 1·00; Chlorine 5·25; Oxygen absorbed ·247
(c) the worst analysis and date when sample was taken;	21st September, 1897: Solids 72·80; Free NH_3 1·092; Alb. NH_3 ·076; Nitrates ·63; Chlorine 11·48; Oxygen absorbed ·490

Date	Solids.	Free NH_3	Alb. NH_3	Nitrates.	Chlorine.	Oxygen absorbed.
20th February 1897:	68·60	·434	·024	1·00	5·25	·247
21st September, 1897:	72·80	1·092	·076	·63	11·48	·490

(d) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters; — None made.

(e) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible? — None made.

(14) Give a typical analysis of the crude sewage to which the experiment relates.

Grains per gallon.

Total solids - - - - - -	211·12
Solids in solution - - - - - -	134·40
Solids in suspension - - - -	76·72
of which mineral 21·00	
organic 55·72	
Free and saline ammonia - - - - - -	2·811
Organic ammonia - - - - -	1·624
Combined chlorine - - - - - - -	9·50
Oxygen absorbed 4 hours - - - - -	16·35

(15) Between what dates was the experiment conducted? If there were any periods of rest, state their duration. — These filters have only been used intermittently, but they have been worked for nine consecutive weeks at one time.

(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths. — Not taken.

(17) Was any nuisance caused by the experimental works. — No.

(18) Is the experiment still proceeding? — No.

If so, may the Commission inspect the works, should they deem it desirable to do so? — Yes.

(19) Give particulars of any other observations of importance which have been recorded. — It has been found that wherever a certain dye class of sewage comes down to the works, it is not desirable to put this on the filters as it rapidly clogs the surface, also the clogging or stoppage takes place on the top of the filter, but does not go above 1 inch in depth.

(20) What inferences have been drawn from the experiment? — These beds will purify the Walsall sewage tank effluent after precipitation, so long as they are not worked at a greater rate than 400 gallons per square yard per 24 hours, and the surface well kept clean and free from clogging, and the sewage is put on to the beds in a "neutral state," except the dye sewage referred to previously, which would choke the beds in a short time.

(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state

(a) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.

(b) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

R. H. MIDDLETON,

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C, Form H.

EXPERIMENT ON THE TREATMENT OF SEWAGE BY CHEMICAL PRECIPITATION, SUBSIDENCE TANKS, AND CONTINUOUS FILTRATION.

Name of authority	Urban District Council of Withnell.
Population of district	3,750 (estimated).
Population of drainage area	2,600.
Water supply per head of the population, as registered by meter at water-works, for district supplied.	Nine gallons per day.
Estimated or measured dry weather flow of sewage	25,000 gallons per day.
Is any trade refuse taken into the sewers?	No.
If so, state from what processes it is derived, and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
	Note.—Storm water is turned into ordinary sewers, when storm sewers are fully charged, to prevent flooding.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Yes.
Officer under whom the experiment has been conducted	T. Beaver, Surveyor.
Name and qualification of chemist who has made the analyses.	No analyses made except by County Council inspector. These were not made to ascertain results of experiments; but for purposes under the Rivers Pollution Prevention Act.

(1) What was the nature of the chemical or chemicals used?	Alumino-ferric.
(2) What was the normal proportion of chemical or of chemicals (in grains per gallon) used?	15.
(3) State whether the chemicals were increased or decreased according to the nature and volume of the sewage treated, and give any particulars of such variations.	Nil.
(4) What is the capacity in gallons of the subsidence tanks?	33,264.
(5) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	20 tons (wet). Tanks cleaned daily.
(6) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(7) (*a*) What are the form, the area and depth of the filters?	Form, oblong. Area, 60 yards sup. Depth, 3ft. of filtering materials.
(*b*) State the nature and size of the filtering material.	1 ft. of large gravel. 3 in. of small gravel. 9 in. of polarite and sand. 1 ft. of sand.
(*c*) Were the ides of the filters open or closed?	Closed.
(8) What was the rate of filtration in gallons per square yard per 24 hours?	500.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extend.	The filters have not choked in the least. They are washed every alternate day.
(9) What was the average quantity of sewage, in gallons, dealt with daily?	About 10,000.
(10) Was the quantity of sewage dealt with increased in time of storm?	No. Passed on to land.
If so, state to what extent, and how the results were affected by such increase.	
(11) State by what method the tank liquor was distributed on the filters.	By iron channel fixed in centre of filters. Tank liquor flowed into channel which overflowed.

Appendix 9C.

(12) State at what intervals analyses of the effluent were made, and whether the samples were filtered though filter paper or allowed to clear by standing, before being analysed.	None made by Council. County Council made analyses, generally satisfactory.
(13) Give (*a*) the average of the analyses of the final effluent from the filters ;	Albuminoid ammonia - - - - - ·060 Oxygen absorbed - - - - - ·23
(*b*) the best analysis and date when sample was taken ; and	May 3rd, 1900. Albuminoid ammonia - - - - ·041 Oxygen absorbed under - - - - ·20
(*c*) the worst analysis and date when sample was taken ;	July 30th 1896. Albuminoid ammonia - - - - ·058 Oxygen absorbed - - - - ·23
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters ;	Not known.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescrible ?	Not known.
(14) Give a typical analysis of the crude sewage to which the experiment relates.	Domestic sewage.
(15) Between what dates was the experiment conducted ?	From 1895 to date.
If there were any periods of rest, state their duration.	No.
(16) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	None taken.
(17) Was any nuisance caused by the experimental works ?	No. (Works close to village.)
(18) Is the experiment still proceeding ?	
If so, may the Commission inspect the works, should they deem it desirable to do so ?	Yes.
(19) Give particulars of any other observations of importance which have been recorded.	
(20) What inferences have been drawn from the experiment ?	That it is desirable for the tank effluent to be good before passing on to filters.
(21) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	Works extended so as to deal with three parts of the sewage, other part being treated on contact beds.
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	Cost of works, £1,000.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	Maintenance : £ Man's wage - - - - - 52 Precipitants - - - - - 12 Other charges - - - - - 6 70

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

THOMAS BEAVER.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

Form K.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority - - - - - - - -	Malvern.
Population of district - - - - - - -	16,000.
Water supply per head of the population - - -	25 gallons per day.
Estimated or measured dry weather flow of sewage -	500,000 gallons per day.
Is any trade refuse taken into the sewers? - - - - If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	We have no trade refuse other than that from a brewery.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially.
Officer under whom the experiment has been conducted -	Engineer and Surveyor.
Name and qualification of chemist who has made the analyses.	C. C. Duncan, F.I.C., F.C.S., &c., analyst for the county of Worcester.
(1) What is the capacity in gallons of the subsidence tanks?	224,000 gallons.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	14 tons. One tank emptied each week.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Intermittent.
(4) (*a*) What are he form, the area and depth of the filters?	160 feet by 78 feet by 5 feet.
(*b*) State the nature and size of the filtering material.	In the experimental filter, constructed in May, 1898, fine coal only was used; latterly filters have been filled with clean clinkers and ashes, varying in size from $1\frac{1}{4}$-inch to $\frac{3}{8}$-inch cube.
(*c*) Were the sides of the filters open or closed? -	Closed.
(5) What was the rate of filtration in gallons per square yard per 24 hours?	About 200 gallons.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	We have had no choking.
(6) What was the average quantity of sewage in gallons dealt with daily.	From 280 to 300,000.
(7) Was the quantity of sewage dealt with increased in time of storm? If so, state to what extent, and how the results were affected by such increase.	Not on the filters.
(8) State by what method the tank liquor was distributed on the filters.	By means of rectangular galvanized carriers perforated in sides and bottoms.
(9) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Monthly. Allowed to clear by standing before analysis.
(10) Give (*a*) the average of the analyses of the final effluent from the filters.	Parts per 100,000: Total solids, 58·98. Chlorine as common salt, 8·856. Free ammonia, 1·19 Albuminoid ammonia, ·38. Oxygen absorbed in three hours, 2·983.
(*b*) The best analysis and date when sample was taken, and	6th March 1899.
(*c*) The worst analysis and date when sample was taken.	24th January 1899.

Appendix 9C.

(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters ;	No record taken.
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible ?	No record taken beyond analyst's returns. The solids were not putrescible.
(11) Give a typical analysis of the crude sewage to which the experiment relates.	Parts per 100,000 : Total solids, 61·28. Chlorine as common salt, 16·352. Free ammonia, 4·00. Albuminoid, ·20. Oxygen absorbed in two hours, 33·08.
(12) Between what dates was the experiment conducted ?	May, 1898, and April, 1899, ten hours each day : viz., from 8 p.m. to 6 a.m.
If there were any periods of rest, state their duration.	
(13) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	None taken.
(14) Was any nuisance caused by the experimental works ?	No.
(15) Is the experiment still proceeding ?	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so ?	Certainly.
(16) Give particulars of any other observations of importance which have been recorded.	
(17) What inferences have been drawn from the experiment ?	That the disposal of sewage by means of subsidence tanks and filters is the surest and most economical way of producing a good effluent.
(18) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	About 4*s.* 2*d.*
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	About 2¼*d.*

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

H. P. Maybury,
Engineer and Surveyor.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form K.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN SUBSIDENCE TANKS FOLLOWED BY CONTINUOUS FILTRATION.

Name of authority	Urban District Council of Rothwell (Northampton).
Population of district	4,500.
Water supply per head of the population	Supplied by wells.
Estimated or measured dry weather flow of sewage	60,835 gallons per day.
Is any trade refuse taken into the sewers?	No.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Excluded from streets.
Officer under whom the experiment has been conducted.	Surveyor.
Name and qualification of chemist who has made the analyses.	None.
(1) What is the capacity in gallons of the subsidence tanks?	12,000 gallons.
(2) State what quantity of sludge was produced weekly in the subsidence tanks, and at what intervals the sludge was removed.	1 ft. Fortnightly.
(3) State whether the flow of sewage through the subsidence tanks was continuous or intermittent.	Continuous.
(4) (*a*) What are the form, the area and depth of the filters?	60 ft. × 18 ft. × 5 ft. deep.
(*b*) State the nature and size of the filtering material	½ in. honeycomb slag chippings.
(*c*) Were the sides of the filters open or closed?	Open.
(5) What was the rate of filtration in gallons per square yard per 24 hours?	250 gallons.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	No.
(6) What was the average quantity of sewage in gallons dealt with daily?	40,000 gallons.
(7) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	50 per cent. not so good.
(8) State by what method the tank liquor was distributed on the filters.	Through 4 in. iron pipes under a head of 3 ft. and distributed in the shape of rain.
(9) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	None.
(10) Give (*a*) the average of the analyses of the final effluent from the filters.	
(*b*) the best analysis and date when sample was taken, and	
(*c*) the worst analysis and date when sample was taken.	
(*d*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the filters.	
(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	

(11) Give a typical analysis of the crude sewage to which the experiment relates.	
(12) Between what dates was the experiment conducted?	One year.
If there were any periods of rest, state their duration.	Month at intervals.
(13) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	
Was any nuisance caused by the experimental works?	Yes.
(15) Is the experiment still proceeding?	Yes, on different lines.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(16) Give particulars of any other observations of importance which have been recorded.	Continuous filtering was found to be unsatisfactory. The tanks have now been enlarged and covered, in and it is intended to work the filter intermittently.
(17) What inferences have been drawn from the experiment?	That by running the effluent over grass land after filtering good results are obtained. We are now completing a scheme whereby the sewage will pass through the covered tank first, secondly through the filter, and then pumped 60 feet high on to a grass field 18 acres in extent collected by a drain at the lower part of the field and finally conveyed on to ploughed land by gravitation.
(18) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	7*s.* 9*d.*
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	6*d.* The total cost of the works is £1,700. The annual cost will be under £100 per year for working the pumping plant and the last is worked at a profit.

Note 1.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus :—

Ammoniacal nitrogen ;
Albuminoid nitrogen ;
Nitrous nitrogen ;
Nitric nitrogen ;
Total organic nitrogen.

Note 2.—The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

W. Z. PEARSORT,
Surveyor to the Council.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

Form M.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE BY CONTINUOUS FILTRATION.

Name of authority	Newmarket Urban District Council.
Population of district	10,000 (estimated), 8,000 contributing to sewage farm.
Water supply per head of the population	About 20 gallons per day, per head. — Cannot give quantity, as company also supply outside urban district.
Estimated or measured dry weather flow of sewage	Average 160,000 gallons per day.
Is any trade refuse taken into the sewers?	No trade wastes in Newmarket.
If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of trade refuse.	No.
Is the storm, soil, or surface water, wholly or partially, excluded from the ordinary sewers?	Storm water partially excluded.
Officer under whom the experiment has been conducted.	The surveyor to the Urban District Council.
Name and qualification of chemist who has made the analyses.	J. West Knights, F.I.C., &c., County Analyst, Cambs.
(1) (a) What are she form, the area and depth of the filters?	Two filters, each 125 feet by 25 feet by 3 feet deep. Area of each filter, 347 square yards.
(b) State the nature and size of the filtering material.	Ashes from the dry dust bins, after being burnt and screened (practically what would be rejected on a ½-inch screen).
(c) Were the sides of the filters open or closed?	Closed.
(2) What was the rate of filtration in gallons per square yard per 24 hours?	100 gallons per square yard.
State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.	No; the outlet valve to filters was kept open and the filters used as open filters, the sewage not being locked in.
(3) What was the average quantity of sewage in gallons dealt with daily?	40,000 gallons.
(4) Was the quantity of sewage dealt with increased in time of storm?	No.
If so, state to what extent, and how the results were affected by such increase.	
(5) State by what method the sewage was distributed on the filters.	By means of wooden carriers on surface of beds.
(6) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing before being analysed.	Approximately, monthly.
(7) Give (a) the average of the analyses of the final effluent from the filters.	parts per 100,000. (a) Albuminoid ammonia - - - - 1·57 Oxygen absorbed at 140° F. (15 minutes) - - - 1·215
(b) the best analysis and date when sample was taken, and	(b) Albuminoid ammonia, ·05, 17th July, 1900. Oxygen absorbed, ·84, „ „ „
(c) the worst analysis and date when sample was taken.	(c) Albuminoid ammonia ·3, 25th January, 1900. Oxygen absorbed, 1·87 „ „ „
(d) the average of the estimations made of the solids in suspension in the sewage as it went on to the filters.	87·87.
(e) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	·16 (trace)

Appendix 9C.

Question	Answer
(8) Give a typical analysis of the crude sewage to which the experiment relates.	Crude sewage: Solids (mineral) - - - - - - - 87·00 „ (organic) - - - - - - - 90·00 Chlorine - - - - - - - - - 16·00 Equal to chloride of sodium (salt) - - - 26·60 Nitrates (expressed as nitrogen) - - - none Ammonia (free) - - - - - - - 15·50 „ (albuminoid) - - - - - - ·70 Oxygen absorbed at 140° F. (15 minutes) - 10·00 Suspended matter - - - - - - 80·00
(9) Between what dates was the experiment conducted? If their were any periods of rest, state their duration.	August, 1899, to September, 1900. One day per week at least.
(10) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	No observations taken of temperatures.
(11) Was any nuisance caused by the experimental works?	No.
(12) Is the experiment still proceeding? If so, may the Commission inspect the works, should they deem it desirable to do so?	No.
(13) Give particulars of any other observations of importance which have been recorded.	My experience of the treatment of domestic sewage on filters containing cinders and ashes dictates that :— (*a*) 80 gallons per square yard per day should be the maximum rate of filtration. (*b*) The minimum depth of material should be three feet, and no particular advantageis gained by making the beds more than four feet deep. (*c*) A period of rest of at least one day in a week should be given. (*d*) Clean screened cinders or clinker (not larger than walnut size) for coarse beds, and (*e*) Coke breeze, clinker, ashes, or coarse sand, for fine beds, passed through a ¼-inch screen will all give good results.
(14) What inferences have been drawn from the experiment?	(*f*) Two operations are necessary, viz., coarse beds and fine beds, to get a satisfactory effluent. (*g*) A prior screening, together with a sedimentation tank before the sewage is run on to the filters, is necessary to avoid choking of beds and consequent diminution of liquid capacity. (*h*) 60 per cent. of purification can be maintained in each operation, or 90 per cent. combined, both on the albuminoid and oxygen absorbed test.
(15) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	About 10*s.* per head.
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	About 6*d.*

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:

Ammoniacal nitrogen
Albuminoid nitrogen
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

JOHN W. METCALF, Surveyor

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C. Form M.

EXPERIMENT ON THE TREATMENT OF CRUDE SEWAGE BY CONTINUOUS FILTRATION.

Name of authority	Stone (Staffs) Urban District Council.
Population of district	5,678.
Water supply per head of the population	19 gallons per day.
Estimated or measured dry weather flow of sewage	257,000 (estimated) gallons per day.
Is any trade refuse taken into the sewers? If so, state from what processes it is derived and, approximately, what percentage of the total dry weather flow of sewage is made up of dry refuse.	Brewery waste from $\frac{1}{3}$ to $\frac{1}{2}$ dry weather flow.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Surface water partially excluded.
Officer under whom the experiment has been conducted.	Under myself, according to directions of Dr. Reid, County Medical Officer, Stafford.
Name and qualification of chemist who has made the analyses.	George Reid, M.D., D.P.H.

(1) (*a*) What are the form, the area and depth of the filters?

Double filtration. Each filter 12 ft. × 9 ft. × 3 ft. 9 in. deep.

(*b*) State the nature and size of the filtering material.

First filter. Engine ashes of sizes from below upwards as follows: 6 in. of 1-in. particles, 6 in. of $\frac{1}{2}$-in. particles 2 ft. 9 in. of $\frac{1}{4}$-in. particles.
Second filter. Coal of sizes from below upwards as follows: 6 in. of $\frac{1}{2}$-in. particles, 6 in. of $\frac{1}{4}$-in particles, 2 ft. 9 in. of $\frac{3}{16}$-in. and $\frac{1}{16}$ in. mixed.

(*c*) Were the sides of the filters open or closed?

Closed.

(2) What was the rate of filtration in gallons per square yard per 24 hours?

Filters worked at the rate of 200 gallons per square yard for a period of 12 hours and then rested 12 hours.

State whether the rate of filtration was reduced during the experiment in consequence of the choking of the filters, and, if so, to what extent.

No.

(3) What was the average quantity of sewage in gallons dealt with daily?

2,400.

(4) Was the quantity of sewage dealt with increased in time of storm?

No.

If so, state to what extent, and how the results were affected by such increase.

(5) State by what method the sewage was distributed on the filters.

Series of transverse tippers supplied from longitudinal troughs, the interval between each tipper being 12 inches.

(6) State at what intervals analyses of the effluent were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.

About three weeks intervals. Neither filtered nor allowed to stand.

(7) Give (*a*) the average of the analyses of the fina effluent from the filters.

Solids, In solution	66·8
Solids, ,, suspension	1·4
Total	68·2
Chlorine	7·0
Ammoniacal nitrogen	0·25
Albuminoid nitrogen	0·11
Nitric nitrogen	0·98
O absorbed in 4 hours at 80° F.	0·68

(*b*) the best analysis and date when sample was taken, and

(*c*) the worst analysis and date when sample was taken.

	(*b*) January 5th 1900.	(*c*) March 28th 1899.
Solids, In solution	67·0	6·2
Solids, ,, suspension	Nil	Nil
Total	67·0	62
Chlorine	6·0	7·2
Ammoniacal nitrogen	0·013	0·215
Albuminoid nitrogen	0·035	0·176
O absorbed in 4 hours at 80° F.	0·308	1·108

(*d*) the average of the estimations made of the solids in suspension in the sewage as it went on to the filters.

39·3 parts per 100,000.

(*e*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?

(1) 1·4; (2) not ascertained.

(8) Give a typical analysis of the crude sewage to which the experiment relates.	Mean of 14 samples. Solids { In solution - 71·0 „ suspension - 39·3 Total - 110·3 Chlorine - 6·7 Ammoniacal nitrogen - 2·16 Albuminoid - 1·48 O absorbed in four hours at 80° F. - 5·11
(9) Between what dates was the experiment conducted?	February 22nd, 1899, to February 7th, 1900.
If there were any periods of rest, state their duration.	Sundays only.
(10) Give particulars of any observations which have been made of the temperatures of the filters at different depths.	No observations made.
(11) Was any nuisance caused by the experimental works?	Nuisance has been complained of.
(12) Is the experiment still proceeding?	No.
If so, may the Commission inspect the works, should they deem it desirable to do so?	
(13) Give particulars of any other observations of importance which have been recorded.	During the experiment a volume of wet sludge, equal to four times the available capacity of one of the tanks, has absolutely disappeared, leaving the filters as clean and free from deposit as when first constructed.
(14) What inferences have been drawn from the experiment?	The plant can dispose of the sewage in question, but it is believed that better results would be obtained by liquefying the sewage in the first instance and a Scott-Moncrieff tank has been put down to pass sewage through before it is discharged on to filters. This is now stopped.
(15) If it is considered that it would be practicable to adopt this system for the disposal of the whole of the sewage of the district, please state	
(*a*) what would be the estimated capital cost per head of constructing the works of disposal, excluding the cost of land and cost of sewers.	
(*b*) what would be the estimated annual cost per head of purifying the sewage by this system, excluding the annual repayment of any loan.	

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

A. R. Ridout, Surveyor.

Signature of Officer under whose direction the experiment was conducted.

Appendix 9C.

BIRMINGHAM, TAME, AND REA DISTRICT DRAINAGE BOARD.

Tyburn, near Birmingham.
January 21st, 1901.

William Harris, Esq., J.P., 9, Bennett's Hill, Birmingham.

Dear Sir,—With reference to the request of the Secretary of the Royal Commission on Sewage Disposal for information regarding any experiments which have been conducted at our works, I beg to say that we have been experimenting on a large scale with open septic tanks, and the results have been to a large extent of a satisfactory kind. First of all a marked reduction in the amount of sludge requiring to be dealt with has been apparent. During the past six months 76,170 cubic yards of sludge have been removed, as compared with 149,170 cubic yards of sludge during the corresponding period of last year. I am satisfied that this result is largely due to the fact that the sewage from our roughing tanks (three in number and having a capacity of 3,000,000 gallons) is passed into 16 open septic tanks, having a total capacity of 4,500,000 gallons, where it is liquefied and peptonised in an extraordinary manner. For a similar period, viz., the six months ending 21st November, the road detritus, which was taken from the first bay of the roughing tanks, showed an increase of quantity equal to 377 cubic yards as compared with last year. During three months prior to 21st November lime had been used as a precipitant; since then no chemical precipitant has been used, and I think there can be no doubt that the cessation of the liming operation contributed towards a more active condition of the septic tanks than during the three months immediately preceding, when milk of lime was added to the sewage prior to its entering the roughing or precipitation tanks. Another benefit which has accrued from the use of the 16 open tanks as septic tanks is to be found in the improvement in the deposit which takes place in the land tile drains; this deposit consists chiefly of a basic compound of iron and iron oxide, and its amount and nature seems to have changed since the septic tank process has been in use; whereas formerly it formed itself into large flakes of a gelatinous nature, it is now much finer and less coherent, and our chemist attributes this to the smaller amount of organic matter present owing to the preliminary action of the septic tank. On analysis he found it to contain:—

Volatile and organic matters.	Nitrogen.	Silica (Sand)	Iron Oxide.	Lime.
34·33	2·30	31·76	24·48	3·58

And Alkalies, etc., 5·85 per cent.

The benefit thus derived from the use of the septic tank, and from the cultivation of the anaerobic organism before the sewage is applied to the land, is a very real one, not so much from the point of view of pollution of the river as from the lessening of the chances of chokage in the land drains.

Another advantage which was found to accrue from the use of septic sewage was the greater fertilizing properties of the sewage, *i.e.* the growth of kohl rabi on field No. 32 was very marked, and the farmer under whose supervision that field was planted tells me that it was better than what was formerly got from the same field when it was well manured with farmyard manure. Again, the rye grass has been particularly good this year, one field yielding no fewer than six crops, and our chemist, whose attention I directed to this, says:—"The septic tank effluent contains large quantities of matter essential to plant growth. This matter is present in a form in which it is more easily available to the plant than it is in the case of the precipitation tank effluent. Also, the septic tank effluent contains much more suspended matter than the other, and this solid matter is spread over the whole area of the farm, and tends to enrich the ground for agricultural purposes."

As it has been suggested by at least one authority that the use of septic sewage on grass or pasture land invariably results in discoloration, and frequently destruction of the crop, I wish to observe that this has not been our experience. I can point to grass land which has been receiving sewage [septic tank liquor G. M.] three days a week, and it is about as green and fresh to-day as it was in the early spring of 1900, when the septic sewage was first applied to it. Generally the quality of the grass all over the farm has been good this year, and when mowed never showed the slightest discoloration at the roots.

I was reluctant to try the effect of septic sewage on land, as I feared that the increased amount of matter in suspension in it, as compared with the sewage formerly sent from Saltley, would tend to clog up the pores of the soil, and probably interfere with the carrying capacity of the great sewer itself. This fear has not been justified in practice. The sewer is as free of deposit now as it was nine months ago, and the filtration bed and land generally is in my view freer of deposit than it was when treated to limed sewage. Even where black scum has been found it dries and cracks readily, and is not of the same indiarubber like quality as the old scum.

I cannot point to any real disadvantage in using septic sewage on land, but there is one point which I think has not been properly settled, and that is whether the limed sewage which formerly flowed on to the land assisted in producing nitrification of the effluent. Our farm is working under abnormal conditions at present, and I do not think we are in a position to form a safe opinion on this subject until the quantity of sewage supplied to the land is reduced from 34,000 gallons per acre to 20,000 gallons per acre in the case of downward intermittent filtration, and this we shall not be able to do for two years to come.

As you are aware, the Works Committee have had a report on this subject under consideration for the past two months, and they have resolved to meet specially to consider whether my recommendation to continue the use of septic sewage, and to abandon the use of lime as a precipitant, should be adopted as a permanent policy. This meeting I expect will be held within the next three weeks.

I am, yours faithfully,

(Signed) JOHN D. WATSON,

Engineer to the Board.

Appendix 9C.

Form.

EXPERIMENT ON THE TREATMENT OF SEWAGE IN OPEN SEPTIC TANK FOLLOWED BY LAND TREATMENT.

Name of authority - - - - - - - -	Birmingham, Tame, and Rea District Drainage Board.
Population of district - - - - - - - -	750,000.
Water supply per head of the population - - -	Probably between 25 and 30 gallons per day.
Estimated or measured dry weather flow of sewage -	25,000,000 gallons per day.
Is any trade refuse taken into the sewers? - - - -	Yes.
If so, state from what processes it is derived, and, approximately, what percentage of the dry weather flow of sewage is made up of trade refuse.	A great variety of trades, the chief of which are connected with brass and iron works. Percentage about one-fifth.
Is the storm, soil or surface water, wholly or partially, excluded from the ordinary sewers?	Partially excluded.
Officer under whom the experiment has been conducted -	The Engineer to the Board.
Name and qualification of chemist who has made the analyses.	F. R. O'Shaughnessy, Assoc. Royal College of Science, Member Society of Public Analysts, &c.
(1) (*a*) What is the capacity in gallons of the open septic tank or tanks?	$4\frac{1}{2}$ million gallons, plus three settling tanks capable of holding $2\frac{3}{4}$ million gallons.
(*b*) If there was more than one tank, state whether they were worked in series or in parallel.	In parallel.
(2) Were any observations made as to the filling up of the septic tanks by deposit of sludge?	When equilibrium was established a small black residue of apparently constant quantity and uniform consistency remained at bottom.
If the sludge was removed from the septic tanks, state how often this was done and, approximately, what quantity of sludge was removed on each occasion.	It has not been necessary to remove any sludge from the septic tanks proper ($4\frac{1}{2}$ million gallons capacity). 76,000 cubic yards of sludge have been removed during the past six months from the large precipitation tanks (capacity $2\frac{3}{4}$ million gallons).
(3) What was the average quantity of sewage in gallons dealt with daily in the septic tanks?	15,000,000.
(4) Was the quantity of sewage dealt with increased in time of storm?	Yes.
If so, state to what extent, and how the results were affected by such increase.	No serious interference was felt till November last, when storm water caused nitrates, etc., to appear, and since then the tanks have not recovered.
(5) State at what intervals analyses were made, and whether the samples were filtered through filter paper or allowed to clear by standing, before being analysed.	Analyses of tank effluent were made as a rule several times per month. When time permitted they were made several times per week. Land effluents were examined oftener. "Free" and "albuminoid ammonias" were determined on unfiltered sample.
(6) Give (*a*) the average of the analyses of the final effluent from the land;	See page 435.
(*b*) the average of the estimations of the solids in suspension in the sewage as it went into the tanks;	See page 435.
(*c*) the average of the estimations made of the solids in suspension in the tank liquor as it went on to the land;	21·1.
(*d*) the average of the estimations made of the solids in suspension in the final effluent. Were these solids putrescible?	It rarely amounts to more than a trace, and is usually sandy when present. A basic precipitate of iron with organic matter forms in the land drains and causes turbidity when these are flushed.
(7) Give a typical analysis of the crude sewage to which the experiment relates.	See page 435.

Appendix 9C.

(8) Between what dates was the experiment conducted?	Between March and November, 1900. The septic tanks required about 2 months, *i.e.* till June, to get into full working order.
If there were any periods of rest, state their duration.	The experiment was continuous.
(9) Was any nuisance caused by the experimental works?	No.
(10) Is the experiment still proceeding? - - - -	Yes.
If so, may the Commission inspect the works, should they deem it desirable to do so?	Yes.
(11) Give particulars of any other observations of importance which have been recorded.	Sludge has been greatly reduced. Suspended matter increased in tank effluent. Exceptionally good crops yielded by land treated with this "septic" sewage.
(12) What inferences have been drawn from the experiment?	Chief inference is that a preliminary septic treatment gives greater efficiency to works and a land effluent better than that from a preliminary chemical treatment.

Note.—It is requested that all analyses may be stated in parts per 100,000, and that the various compounds of nitrogen may be given in terms of nitrogen, thus:—

Ammoniacal nitrogen;
Albuminoid nitrogen;
Nitrous nitrogen;
Nitric nitrogen;
Total organic nitrogen.

JOHN D. WATSON, Assoc.M.Inst.C.E.
Signature of Officer under whose direction the experiment was conducted.

ANSWERS TO QUESTIONS IN THE ABOVE FORM.

(6) *a.* Analyses of final effluent from the land.

Dissolved Solids.	Suspended Matter.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.	Nitrates, &c. as Nitrogen.	Oxygen absorbed.	Name of Outfall Carrier.
112·3	Trace	·96	·07	13·8	·31	1·09	Castle Bromwich.
113·8	3·5	·56	·09	6·5	·15	1·05	Plants Brook.
81·0	Trace	1·52	·11	11·1	·23	1·33	Lowe's Carrier.
89·5	0·5	1·66	·10	12·4	·26	1·62	Water Orton.

The above are some average analyses of principal outfall effluents. The analyses of different individual fields vary widely, the quality depending on the field. Compared with the latter the above show some dilution from small streams and probably also subsoil water.

(6) *b.* Analyses of sewage from principal sewers.

Dissolved Solids.	Suspended Matter.	Ammoniacal Nitrogen.	Albuminoid Nitrogen.	Chlorine.	Nitrates, &c. as Nitrogen.	Oxygen absorbed. Filtered.	Oxygen absorbed. Unfiltered.	Total Organic Nitrogen.	Name of Sewer.
156·0	51·8	2·27	·99	12·6	·35	7·30	14·62	4·06	Saltley.
138·2	47·5	3·09	1·45	23·9	·62	11·85	16·92	3·65	Rea.
139·3	59·6	2·73	1·22	21·8	·91	5·38	12·79	6·87	Hockley.
94·6	47·6	3·14	1·38	10·8	·26	—	9·85	6·88	Aston.

The bulk of the sewage treated is brought to the works by the above four sewers. The contents of these sewers are mixed in the preliminary settling or "roughing" tanks.

(6) *d.* Analysis of growth in land drains.

Volatile and Organic Matter.	Total Nitrogen.	Silica (Sand).	Iron Oxide and Alumina.	Lime (CaO.)	Undetermined matter.
Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
34·33	2·30	31·76	24·48	3·58	5·85

VICTORIA R.

Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith: To Our Right Trusty and Right Well-beloved Cousin, Walter Stafford, Earl of Iddesleigh, Companion of Our Most Honourable Order of the Bath; Our Trusty and Well-beloved Sir Richard Thorne Thorne, Knight Commander of Our Most Honourable Order of the Bath, Medical Officer of the Local Government Board; Our Trusty and Well-beloved Constantine Phipps Carey, Esquire, Lieutenant-Colonel and Honorary Major-General on the Retired List of Our Army; Our Trusty and Well-beloved Charles Philip Cotton, Esquire; Our Trusty and Well-beloved Michael Foster, Esquire, Master of Arts, Professor of Physiology in Our University of Cambridge; Our Trusty and Well-beloved Thomas Walter Harding, Esquire, Retired Lieutenant-Colonel of Our Auxiliary Forces, with Honorary Rank of Colonel; Our Trusty and Well-beloved Thomas William Killick, Esquire; Our Trusty and Well-beloved William Ramsay, Esquire, Professor of Chemistry, University College, London; and Our Trusty and Well-beloved James Burn Russell, Esquire, Doctor of Medicine, Master of Surgery: Greeting!

Whereas We have deemed it expedient that a Commission should forthwith issue to inquire and report:

1. (1) What method or methods of treating and disposing of sewage (including any liquid from any factory, or manufacturing process) may properly be adopted, consistently with due regard for the requirements of the existing law, for the protection of the public health, and for the economical and efficient discharge of the duties of local authorities; and

   (2) If more than one method may be so adopted, by what rules, in relation to the nature or volume of sewage, or the population to be served, or other varying circumstances or requirements, should the particular method of treatment and disposal to be adopted be determined; and

2. To make any recommendations which may be deemed desirable with reference to the treatment and disposal of sewage;

Now know ye, that We, reposing great trust and confidence in your knowledge and ability, have authorised and appointed, and do by these Presents authorise and appoint, you, the said Walter Stafford, Earl of Iddesleigh, Sir Richard Thorne Thorne, Constantine Phipps Carey, Charles Philip Cotton, Michael Foster, Thomas Walter Harding, Thomas William Killick, William Ramsay, and James Burn Russell to be Our Commissioners for the purposes of the said Inquiry.

And, for the better effecting the purposes of this, Our Commission, We do by these Presents give and grant unto you, or any three or more of you

full power to call before you such persons as you shall judge likely to afford you any information upon the subject of this Our Commission; and also to call for, have access to, and examine, all such books, documents, registers, and records as may afford you the fullest information on the subject, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And We do by these Presents authorise and empower you, or any three or more of you, to visit and personally inspect such places as you may deem it expedient so to inspect for the more effectual carrying out of the purposes aforesaid.

And We do further by these Presents will and ordain that this Our Commission shall continue in full force and virtue, and that you, Our said Commissioners, or any three or more of you, may from time to time proceed in the execution thereof, and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

And We do further ordain that you, or any three or more of you, have liberty to report your proceedings under this Our Commission from time to time, if you shall judge it expedient so to do.

And Our further Will and Pleasure is that you do, with as little delay as possible, report to Us under your hands and seals, or under the hands and seals of any three or more of you, your opinion upon the matters herein submitted for your consideration.

And for the purpose of aiding you in such matters, We hereby appoint Our Trusty and Well-beloved Frederick James Willis, Esquire, to be Secretary to this Our Commission.

Given at Our Court at Saint James's, the Seventh day of May, One thousand eight hundred and ninety-eight, in the Sixty-first Year of Our Reign.

By Her Majesty's Command,

(Signed) M. W. Ridley.

William Henry Power, Esq., F.R.S.,
To be a Member of the Royal Commission on Sewage Disposal.

VICTORIA, R.

Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland, Queen, Defender of the Faith: To Our Right Trusty and Well-beloved William Henry Power, Esquire, Fellow of the Royal Society, Medical Officer of the Local Government Board: Greeting!

Whereas We did, by Warrant under Our Royal Sign Manual, bearing date the Seventh day of May, One thousand eight hundred and ninety-eight, appoint Our Right Trusty and Right Well-beloved cousin Walter Stafford, Earl of Iddesleigh, Companion of Our Most Honourable Order of the Bath, together with the several Gentlemen therein mentioned, or any three or more of them, to inquire into the treatment and disposal of sewage.

And Whereas One of the Commissioners so appointed, namely, Sir Richard Thorne Thorne, has since deceased.

Now know Ye, that We, reposing great confidence in you, do, by these presents, appoint you, the said William Henry Power, to be one of Our Commissioners for the purpose aforesaid, in the room of the said Sir Richard Thorne Thorne, deceased, in addition to, and together with, the other Commissioners whom we have already appointed.

Given at our Court, at Saint James's, the Seventh day of February, One thousand nine hundred, in the Sixty-third Year of Our Reign.

By Her Majesty's Command,

(Signed) M. W. Ridley.

Whitehall, March 18th, 1901.

The King has been pleased to issue a Commission, under His Majesty's Royal Sign Manual, to the following effect:—

EDWARD, R.

Edward the Seventh, by the Grace of God, of the United Kingdom of Great Britain and Ireland King, Defender of the Faith, to all to whom these Presents shall come, Greeting!

Whereas it pleased Her late Majesty from time to time to issue Royal Commissions of Inquiry for various purposes therein specified:

And Whereas in the case of certain of these Commissions, namely, those known as—

The Historical Manuscripts Commission;
The Horse Breeding Commission;
The Local Taxation Commission;
The Port of London Commission;
The Salmon Fisheries Commission; and
The Sewage Disposal Commission;

the Commissioners appointed by Her late Majesty, or such of them as were then acting as Commissioners, were, at the late demise of the Crown. still engaged upon the business entrusted to them :

And whereas We deem it expedient that the said Commissioners should continue their labours in connection with the said inquiries notwithstanding the late demise of the Crown :

Now Know Ye, that We, reposing great trust and confidence in the zeal, discretion, and ability of the present members of each of the said Commissions, do by these Presents authorize them to continue their labours, and do hereby in every essential particular ratify and confirm the terms of the said several Commissions.

And We do further ordain that the said Commissioners do report to Us under their hands and seals, or under the hands and seals of such of their number as may be specified in the said Commissions respectively, their opinion upon the matters presented for their consideration ; and that any proceedings which they or any of them may have taken under and in pursuance of the said Commissions since the late demise of the Crown, and before the issue of these Presents shall be deemed and adjudged to have been taken under and in virtue of this Our Commission.

Given at Our Court at Saint James's, the fourth day of March, One thousand nine hundred and one, in the First Year of Our Reign.

By His Majesty's Command,

(Signed) CHAS. T. RITCHIE.

SECOND REPORT.

TO THE KING'S MOST EXCELLENT MAJESTY.

MAY IT PLEASE YOUR MAJESTY,

We, the undersigned Commissioners appointed to inquire into the subject of the Treatment and Disposal of Sewage (including any liquid from any factory or manufacturing process), desire humbly to submit to Your Majesty the following Reports which have been made by the officers appointed by us for the purpose of our investigations :—

(1) The Oxidation of Sterile Sewage. By *Mr. Colin C. Frye.*

(2) The Manchester Experiments.
By *Professor Boyce* and *Dr. G. McGowan.*

(3) Bacteriological Standards in relation to potable and non-potable streams. By *Dr. A. C. Houston.*

(4) Anthrax in Yeovil Sewage. By *Dr. A. C. Houston.*

(5) The Subcutaneous Injection of Animals. By *Dr. A. C. Houston*

(6) The Longevity of B. Typhosus in Sewage.
By *Dr. A. MacConkey.*

(7) Effect of Filtration in reducing the number of Bacteria in Sewage Effluents.
By *Professor Boyce* and *Drs. MacConkey, Grünbaum,* and *Hill.*

(8) The Pollution of the River Severn in the Shrewsbury District.
By *Professor Boyce* and *Drs. MacConkey. Grünbaum* and *Hill*

(9) The Self-purification of the River Severn. By *Mr. Colin C. Frye.*

(10) Some of the chief methods used in the Bacteriological Examination of Sewage and Effluents. By *Dr. A. C. Houston.*

We regret to have to state that since the issue of our previous Report, Mr. Thomas William Killick and Mr. Charles Philip Cotton have found it necessary to resign their seats on the Commission.

(Signed) IDDESLEIGH (*Chairman*),
C. PHIPPS CAREY,
M. FOSTER,
T. WALTER HARDING,
WILLIAM RAMSAY,
JAS. B. RUSSELL,
W. H. POWER.

F. J. WILLIS, Secretary,
7th July, 1902.

CONTENTS.

THE OXIDATION OF STERILE SEWAGE.

It has long been known that sterile sewage undergoes no change when kept, and it was with the object of ascertaining whether or not this held when sewage is exposed in thin films to the air that these experiments were made.

The experiments were made in three series, which may be given under the following heading:—

I. Filtration of sewage sterilised by the addition of mercuric chloride.

II. Filtration of sterile sewage through a sterile filter, the sterilisation in this case being obtained by repeated exposure to steam at 100 deg. C.

III. Filtration of sterile sewage through a non-sterile filter.

The object in each particular series being:—

I. To show the absence of oxidation in sterile sewage as it passes through the filter.

II. To show the results of No. 1 was not due to the mercuric chloride *per se*.

III. To show that the results obtained from No. 2 were not due to the use of heat, but to the absence of bacteria.

I.

For this experiment well-settled sewage containing ·05 per cent of mercuric chloride was allowed to trickle continuously through an open filter 4 ft. long and 9 in. diameter), composed of rough coke, the effluent being collected from time to time.

For purposes of comparison sewage containing no mercuric chloride was allowed to pass at the same rate through an exactly similar filter.

The coke in both cases was taken direct from the No. 2 Whitaker Bed, at Leeds, and was therefore fully matured at the start.

The filters worked for one month, during which time the average percentage purification (three analyses) of the sewage passing into each filter was as follows:—

——	Filter A. Receiving Sewage containing Mercury.	Filter B. Receiving Normal Sewage.
Percentage Purification.	14	47

The more important result, however, was the production of nitrate and nitrite nitrogen, and this in the case of each analysis was:—

—	Filter A.		Filter B.	
	Nitrite Nitrogen.	Nitrate Nitrogen.	Nitrite Nitrogen.	Nitrate Nitrogen.
(1)	Trace - -	None - -	·114	·360
(2)	None - -	·080	None - -	·320
(3)	None - -	·030	None - -	·354

and to take this as a test of oxidation is to say that the oxidation which took place in the sewage containing the mercuric chloride was exceedingly small.

II.

Filtration of sterile sewage through a sterile filter, the sterilisation being obtained in this case by means of steam at 100 deg. C.

For this experiment steam sterilised settled sewage was run through a small filter (2 ft. long and 2 in. diameter), which was enclosed in a glass tube, and the results again compared with those given by a similar filter which was treating normal settled sewage.

The life of these filters was two months, and the figures of five analyses made during this time show the following average percentage purification:—

——	Sterile Filter A. Sewage.	Filter B. Sewage.
Percentage purification -	17	42

The production of nitrate and nitrite nitrogen in parts per 100,000 for this series was:

—	Sterile Filter A.		Filter B.	
	Nitrite Nitrogen.	Nitrate Nitrogen.	Nitrite Nitrogen.	Nitrate Nitrogen.
(1)	None - -	·050	·020	·140
(2)	None - -	None - -	None - -	·123
(3)	None - -	None - -	·051	·535
(4)	Trace - -	None - -	Trace - -	434
(5)	None - -	·030	None - -	·640

and therefore the results both in average percentage purification and in the production of nitrates show a remarkable agreement with those obtained from experiment No. I.

III.

Filtration of steam sterilised sewage through a non-sterile filter.

This was practically a repetition of experiment No. II., except that sewage sterilised by means of steam at 100 deg. C. was allowed to run on to both the sterile and non-sterile filters.

The percentage purification given by the two filters under these conditions, for one analysis, was:—

——	Sterile Filter A. receiving Sterile Sewage.	Normal Filter B. receiving Sterile Sewage.
Percentage Purification.	15	38

and the production of nitrate and nitrite nitrogen:—

Sterile Filter A.		Filter B.	
Nitrite Nitrogen.	Nitrate Nitrogen.	Nitrite Nitrogen.	Nitrate Nitrogen.
None - - -	·030	None - -	·640

So the result from this experiment is, therefore, in agreement with those obtained from the former ones.

Conclusion.

The average percentage purification for all the experiments works out as follows:—

——	Sterile Filters.	Normal Filters.
Percentage Purification	15	42

Or, in other words, the sterile filters did about one-third of the work done by the normal filters.

The average production of nitrate and nitrite nitrogen for all the experiments has been:—

Sterile Filters.		Normal Filters.	
Nitrite Nitrogen.	Nitrate Nitrogen.	Nitrite Nitrogen.	Nitrate Nitrogen.
Trace.	·027	·017	·452

and the oxidation of the sterile sewage as measured by these was therefore one-seventeenth of the oxidation which took place in the normal sewage.

I conclude, therefore, that the oxidation of sewage containing no bacteria is very slow, or, in other words, that the chemical oxidation due to the oxygen in the atmosphere is unappreciable.

The bacteriological analyses for this work have been made by Dr. MacConkey at Liverpool.

(Signed) Colin C. Frye.

Leeds, May 10th, 1900.

REPORT OF PROFESSOR BOYCE UPON THE TREATMENT OF THE MANCHESTER SEWAGE BY MEANS OF BACTERIAL BEDS.

The Finding of the Experts.

On October 30th, 1899 an Experts' Report on the treatment of the Manchester Sewage was published. The report was in favour of adopting a bacterial method of treatment. The experts arrived at this conclusion partly as the result of experiments made by Sir Henry Roscoe and subsequently by Mr. Fowler, and also as the result of a year's observation of experimental beds which they themselves had constructed. The experts being favourably impressed with the bacterial method of treatment, especially directed their attention to

1. "Whether the trade refuse in Manchester sewage seriously impaired the efficiency of the bacteriological treatment.

2. "Whether a portion at any rate of the sludge can be destroyed by bacterial agency.

3. "Whether the addition of chemicals to the sewage before bacteriological treatment can be dispensed with.

4. "Whether the aërobic process (decomposition of organic matter by bacteria in the presence of air) or a combination of anaërobic (similar decomposition without air) and aërobic processes is the more advantageous."

The experts early noted the diminution in the capacity of the beds and concluded that :

1. "The suspended matter must be removed as far as possible by sedimentation.
2. "Any suspended matter not so removed should be retained as far as possible on the surface of the bed.
3. "For maintaining the efficiency of such beds, the surface must be raked or forked over from time to time.
4. "Periodical intervals of rest must be allowed."

Thus they state that septic tanks should be used for :

(*a*) "Protecting the contact beds from receiving not only the mineral detritus of the crude sewage, but also as much as possible of the suspended organic matters contained in the latter.

(*b*) "That as much as possible of the suspended organic matter deposited during the passage of the crude sewage through these tanks should be destroyed by the well-known anaërobic bacterial processes taking place in cesspools and the like

(*c*) "That the sewage actually passing on to the bacterial beds should by means of these tanks be not only free from suspended matter, but also rendered of more uniform character, and thus prevent the excessive demands otherwise made at times upon the bacterial activity of the beds.

(*d*) "That after having undergone the anaërobic processes in the tanks, the liquid would be in a condition to more readily undergo nitrification."

With regard to the treatment of the increased flow during rain (storm water) they state that :

"It is evident that a distinction must be drawn between the first flush of a storm and the highly-diluted sewage which follows, the latter alone being properly designated as storm water. The detailed analysis in connection with the above experiments indicated that the "first flush" lasts, in the case of Manchester, from two to four hours, according to circumstances."

They conclude therefore that :

1. "Provision must be made for the storage of the 'first flush' of sewage at the beginning of a storm.
2. "It is probable that accelerated treatment may be commenced about two hours after the augmented flow has begun to reach the works.
3. "Adequate purification of storm water can be effected by short double contacts, or in the case of extreme dilution even by single contact, the length of the cycle being inversely proportional to the flow of sewage.
4. "When, after a storm, ordinary treatment is resumed, the beds have been proved by experiment to show no decrease in purifying efficiency."

They finally conclude :

That the bacterial system is that method best adapted for the Manchester sewage.

That double contact is best.

That the sewage should be first passed through a septic tank.

That the open septic tank is as efficacious as the closed, that:

"In order that a bacterial contact bed may exercise its full powers of purification, it is necessary—

(*a*) That it should be allowed sufficiently frequent and prolonged periods of rest.

That the sewage applied to it should, as far as possible, be free from suspended matters;

(*c*) That the sewage applied to it should be of as uniform a character as possible.

That the capacity of bacterial contact beds has been found to remain practically constant after they have been in operation for a period of three months.

That in the event of a bed having been unduly taxed, its efficacy is only temporarily impaired and can be restored by a few days' repose.

That the bacterial system of treatment is efficacious at all seasons of the year.

Analysis of the Experts' Report.

The report of the experts is largely based upon observations of their own, extending over a period of one year. This is in my opinion too short a period in which to come to a definite conclusion, especially as regards the life of a bed.

They make no mention of the bacterial condition of the effluents, and have tested the purity of the effluents by chemical means only.

The following is a brief analysis of the chief points in the finding of the experts, together with my own experiments and observations.

1. "*Does the trade refuse in Manchester sewage seriously impair the efficacy of the bacterial treatment?*"

I agree with the experts that it does not. The most striking feature of the Manchester sewage is its tar-like odour. To the presence of tar compounds I attribute the comparatively small number of B. coli in the sewage, and septic tank liquors as compared with Leeds or Liverpool. A domestic sewage is far richer in B coli. Whilst the nature of the Manchester sewage will tend to eliminate pathogenic forms, a fact which is shown by the increased diminution of the B coli during the stay in the septic tanks, and by experiments in the laboratory, the efficacy of the beds is not interfered with; this is shown both by the chemical analyses of the experts and my own bacteriological results, which demonstrate a further diminution in the number of the B. coli. As additional proof that bacterial activity is not checked in the beds, I have found that the effluent from the rough bed (first contact bed) is prone to undergo putrefaction; its odour contrasting markedly with that of the septic tank liquor which flows on to it.

2. "*Is a portion at any rate of the sludge destroyed by bacterial agency?*"

Numerous experiments show that a portion of the sludge is destroyed; this was demonstrated in my early oxidation experiments. But to determine the amount of sludge destroyed on a practical scale, prolonged observation is necessary, and the period of one year of observation by the experts appears to me to be too short.

In the Experts' Report (October 30th, 1899) they state that after some nine months, during which the open septic tank had been in use, the "only notable quantity of sludge which can be perceived, on dipping with a rod, is immediately beneath the inlet penstocks." But six months afterwards (last April), when I took measurement of the same tank, one half of its capacity had been reduced by sludge, whilst the small settling tank which fed it was full. At the same time a very large amount of sludge in suspension, as shown by centrifugalisation, was passing over the lip of the tank. The destruction of sludge is not a rapid process. We determined this in the case of observations upon the Leeds sewage, and by experiments on sludge in the laboratory. The sludge of a manufacturing town is more resistant than that of a domestic sewage which contains more readily putrefactive elements. There is also a very considerable inorganic residue, as the following experiment shows.

Twelve grammes of sludge obtained from the open septic tank (Manchester, April 3rd, 1900) were carefully dried.

The dried sludge weighed 1·442 grammes. After careful incineration the residue weighed ·814 grammes.

This experiment shows that more than one-half of the dried sludge consists of inorganic material. Depending therefore upon the source of the crude sewage, I conclude that the septic tank will gradually sludge up and the more the tank tends to sludge the more sludge in suspension is carried over into the contact beds, owing to the disturbance of the gradually rising floor of sludge. It is worthy of note that the dried sludge of Manchester burns readily when heated.

As in the case of the open septic tank, the closed septic tank shows an increasing deposit and the presence of much suspended sludge in the effluent. The following figures show the amount of sludge precipitable by centrifugalisation in 600 cc. of the effluent from, 1, the open septic tank, 2, the Cameron tank, and 3, a tank in which chemical precipitation is used.

Open septic tank contains	-	·7 cc. in 600 cc.
Cameron tank ,,	-	·5 cc. ,, ,,
Precipitating tank ,,	-	·1 cc. ,, ,,

(The precipitating tank is cleansed at frequent intervals, whilst the other two have not been disturbed since they were started.)

The chemical analyses of the effluents of the contact beds show that a very great degree of purification takes place and that therefore destruction of organic matter is going on. This is at the expense of a gradual reduction in capacity of the bed. The experts are of opinion that the early decrease in capacity is due to the material of the bed becoming clothed with spongy bacterial growths. If this is so, one would expect the growth to increase, but they state that after a comparatively short space of time the beds acquire a practically constant capacity. On the other hand the figures given by Mr. Fowler of the capacities of the beds from March, 1899, to March 1900, show a gradual diminution of capacity. This is in accord with our own observations at Leeds and Liverpool, extending over a period of one year. The experts state that the increase of the capacity in the beds after long periods of rest is due to the removal of oxidisable organic matter entangled in the body of the beds. I agree that the destruction of solid organic matter takes place most advantageously during the period of rest in the moist bed. This is well demonstrated in the comparatively rapid destruction of solid organic materials when worked into ploughed land, and in the method of freeing bone from attached structures, by covering with damp sand, &c. But as in the case of the sludge of the septic tank, so in the case of the contact bed, there is an increasing accumulation of inorganic material. It has occurred in connection with the land of the sewage farm, and leads there to the gradual diminution of porosity. That, in the case of the Manchester experimental beds, a large quantity of suspended material, partly organic and partly inorganic, is continually poured on to them will be seen from the figures already given of the amount of suspended matter in the septic tank effluent and of the amount of inorganic residue in the dried sludge of the tank.

But the experts recognised the danger of permanent loss of capacity, for they early introduced in their experiments the septic tank as a preliminary treatment in order that the "*sewage passing in the beds should be free from suspended matter.*" They early relegated the destruction of the solid organic material to the septic tank. The working, therefore, of the septic tank must be as carefully watched and regulated as the contact bed, or otherwise a large amount of suspended sludge passes over. The experts also state that "any suspended matter not so removed (septic tank treatment) should be retained as far as possible on the surface of the bed." I agree with this, and instance the case of water filtration through sand, where a felt-work accummulates on the surface, and then is skimmed off, but even here clogging of the deeper layers of sand occurs, and necessitates periodical washing. I may also mention that in the case of the Liverpool experiments at West Derby, where the crude sewage has been run directly on to coarse beds, the accumulations of sludge throughout the beds has been very great (these beds are now under observation), but in the finer beds a layer has formed on the top, which has protected the rest of the bed. Mr. Fowler informs me that diminished capacity corresponds, within limits, to increased chemical efficiency. This is in accord with the early observations upon the mode of action of contact beds which I brought to the notice of the Commission. I pointed out that the beds had a filtering action, and that this action was increased by the use of fine material.

Can the addition of chemicals to the sewage before bacterial treatment be dispensed with?"

The experts' report is against the use of chemical precipitation. But it was first thought that the beds would get rid of the sludge difficulty. We have seen, however, the experts soon recognised that some process must take the place of the precipitating tank, and so the septic tank was used. At Chorley we demonstrated by a long series of experiments how efficacious thorough chemical precipitation, followed by filtration, might be; and we brought to the notice of the Commission similar processes in use in Germany. It is a question of expense. If the septic process is used it will be noted from what has been stated above that sludge will still accumulate, and will require to be removed. It is of interest to note that in my observations at Manchester I have found the sludge of the precipitating tank much more prone to putrefactive decomposition than that of the septic tank. We have before pointed out the objections to lime sludge. The precipitated sludge burns on ignition with a luminous flame.

Disadvantage of lime-precipitated sludge.

4. "*Is the aerobic process or a combination of the anaerobic and aerobic processes the most advantageous?*"

As pointed out in the preceding pages, the experts concluded that the combination was the best. From my own observations I agree with this, provided that the septic process is made more perfect than at present and suspended sludge be prevented from passing over on to the beds. Our experiments at Leeds and Manchester show that the B coli diminishes during the stay in the septic tank, and experiments conducted in the laboratory show that the septic tank liquor is inimical to the B. coli and therefore to the other more delicate pathogenic bacteria.

The septic tank process to be perfected.

Thus in one series of observations at Manchester, average number of B. coli per cc. was—

Septic tank tends to kill pathogenic organisms.

Crude sewage	- - - -	5,011
Septic tank	- - - -	2,130
Cameron tank	- - - -	2,099

And in another series—

Crude sewage	- - - -	45,600 per cc.
Septic tank	- - - -	3,433

Keeping the septic tank liquor for two days, the number had gone down to 2,025 per cc.

With the finding of the experts that before going into the contact beds the suspended matter must be removed by sedimentation, that if any passes over, it must be retained as far as possible on the surface of the bed, that the surface of the beds must be raked over from time to time and that periodical intervals of rest must be allowed, I agree from experience gained from experiments with contact beds. But the experience is hardly long enough to enable us to say definitely that the septic tank is the best means of bringing about the sedimentation and the destruction of the solid material of sewage. Rest is essential for reasons before stated. But the length of the rest, or in other words how long contact beds will have to be thrown out of work, and what provision must be made for this, are points which demand prolonged observation. With regard to the recommendations of the experts concerning storm water, I agree that it is essential that it should be treated. My observations of storm water at West Derby show that there are a very large number of organisms present, and that rapid filtration only effects a partial reduction in the number. There is no doubt, however, of the beneficial effect of the filtration, but it should be made as perfect as is the case for ordinary sewage. This is not difficult, seeing that the storm water beds will not be constantly used, and that therefore there will be long periods of rest for recuperation.

The treatment of storm water must be made as perfect as that of ordinary sewage.

The experts finally conclude that the bacterial system is the best method for the Manchester sewage; that there should be double contact beds; and that the sewage should first be treated in the septic tank.

There is no doubt that this method yields good chemical results. Bacteriological analyses show that the first contact bed (Bed A) yields 331,700 bacteria per c.c., and 1,420 B. coli per c.c. The final contact bed (Bed D) gives 115,100 bacteria per c.c. and 329 B. coli per c.c. Speaking broadly, the experts say that in the first contact bed 50 per cent. of the dissolved impurity is removed, and in the final (second) contact 50 per cent. of the impurity still remains, and I might say the same bacteriologically.

Taking the B. coli as index of direct fœcal contamination and as index of the other pathogenic bacteria of which we are aware, I have pointed out that the Manchester sewage compares favourably with other sewages as regards the number of B. coli; that these organisms undergo a still further reduction in the septic tanks and finally, an effluent is yielded from the second contact bed, which contains the B. coli in still fewer quantity. From the information which we have gained from our River Severn experiments, I do not think that 300 B. coli per c.c. passing into the Ship Canal will cause harm. At present the Ship Canal contains some 6,000 B. coli per c.c. above the sewage outfall. Accepting the 300 B. coli per c.c. as an admissible limit, can this standard be maintained? The experts, as I have already shown, state that no solid organic impurities must go on the beds. The septic tank, as at present worked, is not preventing this, and further precautions will have to be adopted. Not only does solid material find its way from the septic tank on to the beds, but the effluents from these still contain a considerable quantity of solid matter in suspension. Thus, in one experiment in 1220 c.c. of

Crude sewage there were	3·6 c.c. deposit,			
Septic tank	"	"	1·7	" "
Bed A	"	"	·5	" "
Bed D	"	"	·7	" "

The nature of the Ship Canal has to be taken into account, and every means adopted to prevent solid matter reaching it. This appears to me to be, in this case, quite as important as the presence of the B. coli. It is clear, therefore, that further observation of the septic tanks and the contact beds is necessary.

APPENDIX.

TABLE showing the NUMBER of BACTERIA and of B. Col. Comm. per c.c. and the presence of the B. Enteriditis Sporogenes.

MANCHESTER.

December 5th, 1900.

Sample.	No. of Bacteria per c.c.	B. Coli Comm. per c.c.	B. Enteriditis Sporogenes.

THE EFFECT OF STAGNATION UPON THE NUMBERS OF BACTERIA AND B. COLI COMMUNIS.

The Bacillus Coli tends to diminish when kept in sewage.

The supernatant fluids of the samples of crude sewage, Septic Tank No. 1 and Beds "A" and "D" (kept from the 3rd to the 18th April) have been examined for the numbers and for the presence of the bacillus coli communis.

Bacillus coli communis, absent in $\frac{1}{10000}$ per c.c. in crude sewage.
Bacillus coli communis, absent in $\frac{1}{10000}$ per c.c. in septic tank.
Bacillus coli communis, present in $\frac{1}{100}$ per c.c. in Bed "A" less than five.
Bacillus coli communis, absent in $\frac{1}{10000}$ per c.c. in Bed "A".
Bacillus coli communis, absent in $\frac{1}{100}$ per c.c. in Bed "D".

TOTAL NUMBER OF ORGANISMS PER C.C.

Crude sewage contains - - -	96,000,000
Septic tank effluent contains - - -	80,000,000
Bed "A" contains - - - -	9,600,000
Bed "D" contains - - - -	6,400,000

In beds "A" and "D" the putrefactive bacilli, *Bacillus fluorescens* and *Bacillus luteus* predominate. These are absent in the septic tank effluent.

It will be observed that whereas the Bacillus coli is considerably diminished by keeping, the multiplication of other forms of bacteria has very greatly increased. It is also worthy of note that the putrefactive forms like the Bacillus fluorescens increase in the beds.

EXAMINATION of the SLUDGE of the OPEN SEPTIC TANK and the PRECIPITATION TANK at Manchester.

By means of six specially constructed glass tubes we made a very thorough examination of the contents of No. 1 Open Septic Tank.

The bottom was covered with sludge to a variable but very considerable depth. It was greatest in amount near the entry of the sewage and was least where the effluent ran off. By means of the glass tubes a sample of the sludge was brought to the surface and portions reserved for microscopical and bacteriological analysis

Microscopical Analysis of Sludge.

Bottom of Sludge of Open Septic Tank.

Colour intensely black, strong tarry odour, develops gas. Microscopical examination shows the deposit to be largely composed of amorphous black granular material, vegetable fibre, wool fibre, cellular tissue ; the vast bulk is amorphous. Cover slip preparation shows a few scattered bacteria and threadlike forms. The number of bacteria is by no means great. A striking feature of the preparation is the absence of any large number of organisms.

Top of Sludge of Open Septic Tank.

The sample is much thinner, with a faint sewage odour. The reaction of the sludge appears to be neutral.

A microscopical examination of the deposit shows much amorphous material. There are, however, more fibres present, cellular debris of various kinds ; sarcinæ and loose cellular tissues are also present. There is a considerable amount of gritty material. The number of bacteria is not great.

A stained cover slip preparation shows that the bacteria are more numerous than in the preceding case. There is still the absence of zoogloea masses.

The dried sludge of the open septic tank burns readily on heating and produces a luminous flame.

Twelve grammes of fresh wet sludge yield after two days drying, 1,442 grammes, and after incineration, ·814 grammes.

Sludge of Precipitation Tank.

Sludge collected as before with the special glass tubes, lighter in colour, distinct tarry odour.

Microscopical examination shows a very much lighter deposit, numerous infusorial forms, vegetable debris, but not as abundant as in the preceding case, wool fibre, threadlike bacteria, one or two diatoms.

I evaporated to dryness the sludge from the precipitation tank, No. 2, and obtained a residue, which like that from the septic tank, yielded luminous gas on heating. It was noteworthy that the sludge had a much more unpleasant decomposing odour than the sludge from the open septic tank.

600 c.c. of the effluent obtained from the following tanks were centrifugalised and yielded :—

Open septic tank - -	·7 cubic centimetres.	
The Cameron - -	·5 „	„
Precipitation tank -	·1 „	„

EXAMINATION of the SUSPENDED MATTER in the OPEN CLOSED and PRECIPITATING TANKS at MANCHESTER.

Samples taken from No. 1, Open Septic Tank ; No. 2, Precipitation Tank, and No. 3, Cameron Tank.

A quantity of the supernatant fluid of each tank was allowed to stand for 12 hours.

Cameron Tank Effluent - -	Deposit black.
Open Septic Tank - - -	Deposit not so dark, but thicker.
Precipitation Tank - -	Lightest.

MICROSCOPICAL ANALYSIS of DEPOSIT of OPEN SEPTIC TANK LIQUOR.

The deposit consists of dark and amorphous granular matter. A considerable number of unicellular green algæ are present. There are no zoogloea masses. Very long threadlike forms of bacteria and remains of wool fibre are present.

The deposit, on the whole, is in a very finely subdivided state, and there is very slight evidence of the original structure of the material from which it is derived. The amount of gritty material seems small.

On addition of potassic ferrocyanide and H.Cl. the greater proportion of the amorphous granular particles give a Prussian blue reaction.

On making a cover glass film of the deposit, and staining with methylene blue, a considerable number of bacteria are demonstrated. There does not appear to be an excessive growth of one particular kind of organism.

DEPOSIT from CAMERON TANK LIQUOR.

Microscopical examination of the deposit shows that the particles are darker than in the open septic tank. They are quite amorphous with the exception here and there of a piece of wool fibre. There are no green unicellular algæ. The threadlike organism is absent and the number of bacteria appears much less. Deposit gives a Prussian blue reaction.

Cover slip preparations stained with methylene blue show a few of the threadlike organisms and bacteria scattered about, but by no means in large numbers nor so abundant as in the case of the open septic tank.

DEPOSIT from PRECIPITATION TANK LIQUOR.

Deposit much lighter in colour, with here and there black granular material. Signs of life much more evident. Unicellular organisms fairly abundant. More evidence of the material of which the sewage is composed, than in either of the preceding cases.

COVER SLIP PREPARATION.

Bacteria much more numerous. Bacteria of all kinds are present. Threadlike organisms, and very numerous short forms, spore forms, spirilla and capsule forms.

April 3rd, 1900.

EXAMINATION OF EFFLUENTS AND DEPOSITS FROM CRUDE SEWAGE, SEPTIC TANK NO 1, AND BED "A" AND BED "D."

Samples have been remaining from the 3rd to the 18th in stoppered bottles which were completely filled with the effluents. Deposits have been thrown down in all bottles and these have been reserved for centrifugalisation. The supernatant fluid in the crude sewage and septic tank has a distinctly tar-like odour and is not unpleasant. That from bed "A," although it is much clearer than the previous effluents and contains much less deposit, yet smells more unpleasantly and has distinctly putrefactive odour. The supernatant fluid from bed "D" is very clear and has a curious grass-like odour. The contrast between the odours of the open septic tanks and the beds is very marked therefore.

DEPOSITS.

Whilst the deposit of the septic tank is very black and abundant, the deposit of bed "A" is very much less, but is still black. The deposit in the case of bed "D' is slight and contrasts with the previous deposits in having a light brown colour and being much more gelatinous, more flocculent and not so heavy.

CENTRIFUGALISATION OF 1,220 C.C. OF THE FOLLOWING FLUIDS YIELDED :—

Crude Sewage - -	3·6 Cubic Centimetres.	
Septic Tank - -	1·7 „	„
Bed "A' - - -	0·5 „	„
Bed "D" - - -	0·6 „	„

The deposit of bed "D" is brown in colour

R. Boyce.

18 July 1900.

18th July, 1900.

An Examination of the two Reports on the proposed New Sewage Disposal Scheme for Manchester, by Dr. G. McGowan, together with some notes of further chemical work in connection with this by Mr. Frye and himself. Written for the Royal Commission on Sewage Disposal, July, 1900.*

Note.—The more purely critical parts of this paper are indicated by a double black line || *at the margin of the paragraph.*

A Summary of the Reports may probably be of some use. They are, however, already very condensed, and to make a summary which is appreciably shorter than the Reports themselves is no easy task. It is therefore hoped that those members of the Commission who have not yet had time to read the Manchester reports, may be able to do so after looking over these notes. A careful study of them, together with Mr. Frye's and my own independent observations and experiments, has left on my mind the impression of the great value of this systematic piece of work, and also of the success which has in the main attended it.

The first Report is dated October 30th, 1899, and is written by Mr. Baldwin Latham, Prof. Percy F. Frankland and Prof. W. H. Perkin, the three Experts consulted by the Rivers Committee. The Supplementary Report is dated December 22nd, 1899, and is written by Mr. Gilbert J. Fowler, under whose able superintendence the experimental work has been carried out; this last includes the records up to December 7th, 1899.

Report. — p. 2. After consultation and inquiry the Experts came to the conclusion "that the only one (scheme) which it was desirable to consider in more detail was the so-called 'Septic Tank' system of Messrs. Cameron, Commin and Martin, of Exeter, and we subsequently arranged that a complete experimental installation should be erected at Davyhulme, according to the plans and under the immediate supervision of the patentees, and the prosecution of exhaustive experiments with the plant so erected has formed an integral part of our inquiry."

pp. 2-3. Visits were made to a number of different sewage works, and the various methods of purification were afterwards summarized, but only the last sentence of this summary need be quoted here :—

> "Thus, for the destruction of impurity, *i.e.*, for the real purification of sewage, there is only one practicable means available, viz., *the employment of bacteria in some shape or form. In fact, all methods of sewage purification actually practised are bacterial methods, whether so named or not.*"

p. 4. On page 4 of the Report, details are given of the amount of land, &c., available at Davyhulme. The ground extends to 165·5 acres, more than amply sufficient, in the opinion of the Experts, for the proposed bacterial scheme. The possibility of utilising the existing works and the special circumstances of Manchester, more particularly the relation of the sewage works to the Ship Canal, were borne steadily in mind.

The present treatment (in bulk) of the Manchester sewage consists in precipitating the screened sewage with sulphate of iron and lime. The liquid, after the precipitate has settled, is run into the Ship Canal, while the sludge is discharged by a sludge steamer into the sea below the Mersey bar. The inadequacy of this treatment has long been the subject of complaint by the Mersey and Irwell Joint Committee, hence three other methods have been considered, viz. :

(1.) Treatment of the effluent on land.
(2.) The Culvert Scheme.
(3.) The Bacterial Scheme, as proposed by Sir H. Roscoe, and modified by the present Rivers Committee.

p. 5. (1.) The possibility of *land treatment* is discussed, but set aside owing to the great initial cost, and the unsuitability of any land likely to be available for the purpose.

p. 6 (2.) The *Culvert Scheme* is likewise rejected, because of (a) the possible nuisance which would be caused in the Mersey; (b) because it would involve the abstraction of 25,000,000 gallons of liquid per day from the Ship Canal; and (c) because of the difficulty (as regards volume) that would be caused by storm water.

Report. — p. 7. The *Bacterial Scheme* was, therefore, found to be the only one to investigate more thoroughly. After reference to the valuable experimental results obtained by Sir Henry Roscoe, and afterwards by Mr. Fowler, in 1896–7, it is pointed out that this plan (of treating chemically-precipitated sewage on bacterial filters) would necessitate, on the large scale, an outlay of 5,000*l.* pe annum for chemicals, and the disposal of 190,000 tons o sludge. Hence it was sought to devise a more economical method.

"Some of the most urgent points demanding elucidation were the following :—

> "1. To determine whether the trade refuse in Manchester sewage seriously impaired the efficiency of the bacteriological treatment."
> "2. To determine whether a portion, at any rate, of the sludge can be destroyed by bacterial agency."
> "3. To determine whether the addition of chemicals to the sewage before bacteriological treatment can be dispensed with."
> "4. To determine whether the aerobic process . . . or a combination of aerobic and anaerobic processes is the more advantageous."

To obtain a reply to these questions, experimental bacterial beds were erected at Davyhulme, and those beds were subsequently added to, in order that storm water as well as sewage might be dealt with, in compliance with a demand made by the Local Government Board. The results of these experiments (which are being continued still) "have enabled us to formulate a definite scheme for dealing with the sewage of Manchester in its entirety, which we have no hesitation in recommending to your Committee for adoption."

Pages 9–12 of the Report are taken up with a short explanation of the actions of different kinds of bacteria, and the conditions under which they best do their work of purification. It is hardly necessary to summarize this.

Description of the Experimental Plant.

(Diagrams 1 and 2 and Photograph 1.)

There are five bacteria beds (concrete), A, B, C, D, and E. A, B, C and D are 33·5 feet square at the top, 17·5 feet square at the bottom, and 4 feet deep. E is 12 feet square at the top, 3 feet square at the bottom, and 4 feet deep. The bottoms of the tanks are channelled, to receive the 6-inch and 2-inch pipes for drawing off the filtrate. The filtering medium is clinker, 3 feet deep. With the exception of the rough material immediately surrounding the pipes, the size of the clinkers is uniform throughout each bed and is as follows :—

Bed A, passed 3-inch mesh, rejected by 1-inch mesh.
" B, " 1 " " " " ¼ " "
" C, " ¾ " " " " ¼ " "
" D, " ½ " " " " ⅛ " "
" E, " ½ " " " " ⅛ " "

The troughs for distributing the sewage and effluents upon the beds are of wood, laid upon the surface of the clinker, and perforated near the bottom so as to give an even distribution over the bed. The supply-pipes were so arranged that the beds could be supplied either with *screened raw sewage*, *settled sewage*, or *open septic tank liquor*. After allowing for the slope of the sides, each bed A, B, C, or D had an effective superficial area of 0·0131 acre (*i.e.*, about $\frac{1}{76}$th of an acre).

> Note.—It is perhaps worth while to point out here that in a small bed of the size and shape of A (see figure), having its sides so sloped that the superficial area at the top of the bed is 3½ times greater than that at the bottom, the aërating conditions must be more favourable than in a large bed (say, of half an acre), in which the slope of the sides would be relatively inappreciable.

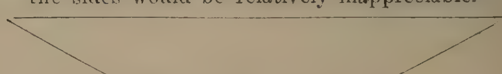

Diagram to Scale.

Treatment of Settled and of Raw Sewage.

During the earlier stages of the experiments, only beds A and B were in operation, their capacities having first been taken (*see* p. 3). For the week ending 21st September, 1898, bed A was filled once a day with

* *Note.*—It is nearly two years since this Report was sent in to the Commission, but it is printed now with little change, only a few small additions and alterations having been made.
May, 1902.

settled sewage and the effluent run on to B, one to two hours' contact being allowed · while from 21st September to 26th October two fillings per day were allowed. A and B having now acquired a high degree of efficiency (as shown by the analyses of the effluent), they were, after 26th October, 1898, filled three times a day with settled sewage, according to a given time table.

Owing to the highly satisfactory results obtained with settled sewage, it was felt that the time had now arrived for ascertaining whether the *raw sewage* of Manchester could be effectively dealt with on the same lines. From 16th November till 14th December, 1898, therefore, raw sewage was run on to the beds at 6 a.m., the other two fillings still consisting of settled sewage. The results with three fillings under those conditions still proving satisfactory, it was decided to experiment with raw sewage entirely, and from 21st December, 1898, to 7th February, 1899, raw sewage alone was admitted. After the latter date it was decided to try the effect upon the bed of *four fillings a day*. For the first week raw sewage was used, but afterwards settled sewage, as it was found that the surface of bed A showed signs of clogging; and this system of working (*see* time-table) remained for the most part in use until the date of the Local Government Board enquiry on 1st May, 1899.

As the treatment of both raw and settled sewage has been abandoned at Manchester (because of the above clogging), nothing further need be said here on the subject.

On December 3rd, 1898, the small extra (fine) bed E was added, which was filled with effluent from B by pumping. It was supplementary to A and B, and its use was discontinued after April 12th, 1899.

The beds C and D were brought into operation on *April 13th, 1899*, C being filled twice a day with settled sewage, and two hours' contact being allowed for each bed.

D was taken up in May, 1900, in order to re-arrange the pipes at the bottom of the bed. C, I think, has never been touched. I understand that Mr. Fowler is supplying to the Commission full details of the working of the beds since the Reports were published.*

After April 10th, 1899, a sunk wooden partition was placed in the settling tank, to keep back suspended matter as far as possible. Previous to this, much had been carried on to the first contact beds.

Measurement of Capacities of Beds A and B.

The beds, when empty, had each a capacity of 10,580 gallons. After the cinders were filled in, the capacities were :—

	A.	B.
September 9th, 1898 -	—	5,688 gallons.
" 12th, " -	5,688	— "

On using, the capacity of A went down gradually as low as—

April 13th, 1899 - - -	3,020 gallons.
April 20th, " - - -	3,350 "

B showed less diminution, as was of course to be expected, seeing that it treated the effluent from A, the lowest point being reached on—

March 7th, 1899 - - -	3,700 gallons.
April 20th, 1899 - - -	4,350 "

The beds had short rests given to them now and then, in addition to the daily rests between the fillings.

The quantities of sewage (settled or raw) dealt with by A and B between September 12th, 1898, and April 20th, 1899 (calculated from the capacitities of bed A at different times), were :—

	Gallons per acre per day.
Maximum, October 27th, 1898 - -	616,981
Minimum, January 10th, 1899 - -	490,499
On April 20th, 1899 - - - - -	574,135
Average of ten gaugings between September 12th, 1898, and April 20th, 1899 - - - - - -	557,313

From his observations on the Leeds beds Mr. Frye thinks that the gain in capacity of a bed, after resting, is due mainly to mechanical shrinkage of the spongy matter present, and only in a lesser degree to oxidation. He bases this view on the fact that the proportion of volatile to non-volatile matter in different sludges—whether these be taken from the interior of a filter bed or from a septic tank—is much the same for a given sewage. (See notes to Appendix F.)

On the other hand, the examination of filter bed gases shows that oxidation goes on actively when a bed is resting. Report.

* *Note.*—For further details upon this point, see the Annual Report of the Manchester Rivers Department for the year ending March 27th, 1901, pp. 61-62. (G.M.—May, 1902.)

The Septic System of Sewage Purification (Cameron, Commin and Martin's patent).

The closed tank used in these comparative experiments is 40 ft. long, 12 ft. wide, and 9 ft. 2 in. high, having an arched roof. From the septic tank, the liquid passes into a shallow aerating trough, over the sides of which it falls in thin sheets into a channel leading to distributing wells, and so on to the beds, which are filled and emptied automatically. There are *six* beds, enclosed by vertical concrete walls, the average area of each bed being 294 square feet, or about 33 square yards (they differ slightly in size). The filtering medium (clinker) is 4 ft. deep, and is arranged from the bottom upwards as follows :— p. 14.

1 ft. to pass 3 in. mesh, rejected by 1 in. mesh. p. 15.

2 ft. 9 in. to pass ¾ in. mesh, rejected by ⅛ in. mesh.

3 in. of residue which passed ⅛ in. mesh.

This installation was got into working order by November 10th, 1898, but difficulty was experienced in adapting the automatic gear to the requirements of the experimental plant; consequently the filling and emptying of the beds was mostly done by hand. The beds were, of course, started gradually, the charges being increased until, from March 17th to April 29th, 1899 (the day of the Local Government Board inquiry), the installation was working eighteen hours per day. p. 19.

Measurement of Bed No. 6 of Septic Installation. p. 24.

	Capacity.	Gallons per Acre per Day.
November 8th, 1898 - -	3,560	—
" 9th " - -	3,330	493,333
April 28th, 1899 - - -	2,820	835,555
September 8th, 1899 - -	2,480	734,814

Roscoe Filters (treating *chemically precipitated* Sewage). p. 15.

These filters are two in number. They were constructed under the advice of Sir Henry Roscoe, and first put into operation on *December 15th, 1895*. After December 15th, 1898, they received four fillings per day. Each filter bed measures 12 ft. 6 in. by 18 ft., giving a surface area of 25 square yards ($\frac{1}{194}$th of an acre). They were filled originally to the depth of 3 ft. with the filtering material, in the one case coke and in the other cinders, graded as follows (beginning with the bottom layer) :—

12 in. rough clinker.

9 in. clinker screened to pass 1½ in. mesh.

6 in. " " " ¾ in. "

6 in. " " " ⅜ in. "

3 in. washed gravel.

Capacities of the Roscoe Filters. p. 21.

	Coke Filter.	Cinder Filter.
At the commencement :	Gallons.	Gallons.
Dec. 19th, 1895 - - -	1,750	1,750
April 26th, 1897 -	1,296	1,260
Oct. 6th, 1897 - - -	1,296	1,264

The full table of capacities given in the Report shows that these filters are now keeping a practically constant

Report. p. 27

capacity. It is noteworthy that by the beginning of this year their depth had increased from the original 3 ft. to 3 ft. 6 in., from the gradual accumulation on the surface of soil produced from the sewage.

The *quantity* of chemically-precipitated sewage dealt with per acre per day in these filters varied between :

———		Coke.	Cinder.
		Gallons.	Gallons.
Maximum, Dec. 19th, 1895		1,016,000	1,016,000
Minima	June 17th, 1898	690,100	—
	April 26th, 1897	—	731,800
	Oct. 6th, 1899	1,004,000	947,800
Average (16 gaugings)		831,400	877,100 (15 gaugings).

On pp. 24–25 of the Report, the foregoing measurements of capacity of the several bacteria beds which were being reported on are summarized and deductions drawn. The following paragraphs may be quoted here :—

"(1.) With regard to the most advantageous grade of material, experience has shown us that the coarse cinders with which bed A was filled permit the free access of sludge, both into the body of the bed and even into the drains below, which sludge not only diminishes the capacity, but is also prejudicial to the purifying efficiency of the bed. On the other hand it is well known that if the material is too fine, the beds soon become quite impervious to sewage. In view of these considerations, we have endeavoured in the case of beds C and D to select material of such grade as shall be free from either of these defects."

"(2.) Respecting the decrease in capacity of a bed noticed in the early period of working, it was observed that the surface of the bed sank . . . . some two inches during the first month, necessitating the addition of a layer of fresh cinders to make the depth of the bed up to the original three feet. This settlement of the material doubtless partly accounts for the early decrease in capacity."

"(3.) . . . . . The spongy bacterial growths also necessarily occupy space, and retain a considerable volume of liquid."

"(4.) As far as time has allowed, it would appear from our experiments that contact beds, after a comparatively short space of time acquire a practically constant capacity, and this conclusion is borne out by the experience gained over a much longer period of time with the Roscoe filters, the measurements of which on April 26th, 1897, and April 26th, 1899, gave identical results."

This analogy between the Roscoe filters and the other contact beds is open to criticism. The former treat chemically-precipitated sewage, from which the iron and tough fibre are presumably settled out.

"It was noted in the case of the Roscoe filters that after the period of constant capacity had set in, the surface of the bed had visibly risen above its original level, and that the layer at the top had become converted more or less into the condition of soil. If the surface when in this condition is allowed to remain too long
p. 37. untouched, it tends to prevent the free percolation of sewage into the body of the bed. On being loosened, however, with a fork, the sewage penetrates into the interior quite freely. This treatment has not been found necessary more than once a month.'

The authors then drew the conclusions :—

"(1.) The suspended matter must be removed as far as possible by sedimentation.

"(2.) Any suspended matter not so removed should be retained as far as possible on the surface of the bed.

"(3.) For maintaining the efficiency of such beds, the surface must be raked or forked over from time to time.

"(4.) Periodical intervals of rest must be allowed.

Chemical Efficiency of the Bacterial Beds.

In order to arrive at this, the sewages, septic tank liquors and effluents have been continuously sampled* and analysed, the results being set forth in a series of diagrams which are easy to follow. The tests which are mainly relied upon are :—

(1.) The 4-hours "Oxygen absorbed" test. *Diagrams 4, 5 and 6.*

(2.) The albuminoid ammonia test. *Diagrams 7, 8 and 9.*

(3.) The incubator test. *Diagrams 10, 11 and 12.*

This last test, devised by Mr. Scudder, is now well known ; but the description of it which is given in the Report may be appended here :—

"A very valuable indication of the degree of impurity of any sewage or effluent is afforded by the so-called incubator test. To carry this out, a determination is first made of the oxygen absorbed from potassium permanganate by the sample in three minutes. A bottle is then completely filled with the sample, and closed and placed in the incubator at 80° F. for six or seven days. The three minutes' oxygen absorption is then again determined. If any putrefaction has taken place, the oxygen absorbed in three minutes will exhibit a decided increase in amount, owing to the more ready oxidizability of the products of putrefaction, such as sulphuretted hydrogen, etc. On the other hand, if the sample keeps sweet, the three minutes' oxygen absorption remains practically unchanged after incubation, or there will be a slight decrease, owing to slight oxidation of the impurities which has taken place during the period of incubation at the expense of the nitrate or dissolved air present in the sample."

Reserving any definite expression of opinion as to the general applicability of the incubator test, it appears to have answered very well with these Manchester effluents.

In addition to the above three tests, the diagrams and tables also give information with regard to the amounts of free ammonia, nitrite, nitrate and chlorine, and also the degree of acidity or alkalinity of the liquid in question. Besides this, a note is made at the top of each diagram of the trade effluents which at any particular date were conspicuously present in the sewage. The diagrams further indicate :—

(*a.*) Whether the sewage dealt with is settled or crude.

(*b.*) The volume of sewage flow per 24 hours.

(*c.*) The impurity in the raw or settled sewage, first effluent from bed A, and second effluent from bed B, in terms of "oxygen absorbed," etc.

(*d.*) The Mersey and Irwell standards.

It will be remembered that the Mersey and Irwell standard is, "*that a gallon of a final effluent shall not show more than 1 grain of 'oxygen absorbed' in four hours, and not more than 0·1 grain albuminoid ammonia.*"

The results of the treatment of raw and settled sewage by the double contact system, as set forth in the report and the diagrams already referred to, were encouraging, but not by any means all that could be desired, the Mersey and Irwell standard being frequently infringed by the final effluent. As may be inferred from the later Manchester experiments, this was no doubt due in great part to the unevenness in composition of the sewage, and the consequent strain upon the filter beds at certain hours of the day ; and to the clogging of the first contact bed. It seems, therefore, hardly worth while to enter into any detailed criticism of these results here, since the Manchester experts, recognising the causes of the above partial failure, long ago gave up the idea of treating raw or settled sewage in favour of septic tank liquor (*see* page 7). They refer, however, at this stage of the report to one or two points which it is well to notice, especially to the fact that the oxidizable matter in the Manchester sewage (as indicated by the "oxygen-absorbed" test) often consists largely of special forms of trade refuse, which are harmless from a putrescible point of view. Thus, several of the final effluent samples, which infringed the "oxygen-absorbed" standard, withstood putrefaction on being submitted to the incubator test.

* Note.—In answer to a question as to how this sampling was done, Mr. Fowler writes (June 10th, 1902) :—
"Comparative samples were obtained in all these cases as follows :—
"The penstocks were so adjusted that the beds filled and discharged at a "constant rate. Samples were then taken every five minutes, and a "mixture of these samples was analysed."

They add : "Indeed it should be clearly borne in mind that the limits of impurity must not be too rigidly interpreted, and that the object of purification is primarily the production of an effluent free from putrescibility, and not one in which the chemical ingredients are below some necessarily more or less arbitrary standard. It was at one time feared that the presence of the manufacturing refuse in Manchester sewage would seriously militate against its successful bacterial treatment, but reference to the diagrams clearly shows that this is not the case, and that the trade refuse present in the sewage is incapable of inhibiting the bacterial process."

"It has indeed been found by one of us, in the course of experiments made in connection with the treatment of sewage from other towns, that certain trade effluents which, like those from tar works, would be expected to exercise a markedly deleterious influence on bacteria, are, when only moderately diluted, without any perceptible influence on bacterial life. Indeed we are of opinion that only in very exceptional cases can trade refuse be present in ordinary town sewage in such proportion as to affect the bacterial processes of purification."

These early experiments also showed that the effluent became better as the beds got older; that, when the sewage was exceptionally weak, only one contact was required; and that, when the cinders in the first contact bed were *too coarse*,* the bed became more or less clogged with suspended matter and failed to do its work properly.

Efficiency of the Cameron Septic Tank Installation.

Diagrams 13 and 14 show that the liquor from the closed septic tank, unlike crude sewage, remains comparatively uniform in composition, being similar in this and other respects to the liquors from the open septic tank. "The filtrate from the contact beds of the septic system is characterized by its frequent, we might almost say its uniform, infringement of the Mersey and Irwell standards; while, on the other hand, it generally resists putrefaction in the incubator test, in consequence of its containing a comparatively high proportion of nitrate.

Efficiency of the Roscoe Filters.

The earlier results from these have already been given in Reports 1896, 7 and 8 (cited). The results obtained in 1898 and up to 17th May, 1899, are given in *Diagrams 15, 16, 17, 18 and 19.*

"An Examination of these shows that although the numerical limit of impurity of the Mersey and Irwell Joint Committee is at times infringed, yet this infringement is not serious.

"The results of the incubator test are uniformly satisfactory, showing that the filters are effective in removing putrescible matter.

"After 15th December, 1898, the filters were filled four times a day, but no appreciable difference in the amount of purification effected is revealed by the curves.

"This result is of importance as bearing out the statement that, as the actual holding capacity of the beds decreases (within a certain limit, of course), the chemical efficiency increases, and a larger amount of work can therefore be put upon them. With four fillings per day (Report, p. 22) the beds are dealing with as much tank effluent as they did when first started, and the chemical results are, if anything, more satisfactory. (*Compare remarks on p. 5.*)

"The cinder filter has, with some incidental exceptions, given better results throughout than the coke filter."

Later Improvements on the Foregoing Methods of Bacterial Treatment, *i.e.*, Introduction of the Open Septic Tank.

Leaving out of account for the moment the Roscoe filters and the Cameron closed septic tank installation, it will be observed that up to this point the Report has dealt with the treatment either of settled sewage or of raw sewage on the bacteria beds. After this, the results obtained by treating *open septic tank liquor* on the beds are given. *And this last is the plan which it is now proposed to adopt on the large scale.*

* Note.—In answer to a recent query with regard to this point, Mr. Fowler writes (May 14th, 1902):—

"I should consider a bed *too coarse* which contained no material below ¼ inch. The grade of a bed is really conditioned by the size of the smallest material present, and the proportion of this to the whole bulk. Our material for the (new) half-acre beds is screened through a $\frac{3}{16}$ inch mesh, and roughly graded by raking down the coarser pieces to the bottom of the bed, as the material is tipped from the wagons."

The objects aimed at in using an open septic tank were to deposit the inorganic detritus and as much of the suspended organic matter as possible, and to get a tank liquor of fairly uniform composition; this, after being subjected to anaerobic decomposition in the tank, would be more ready to undergo subsequent nitrification. Beds A and B were also remodelled. The drain pipes of B had become blocked with fine material, so the pipes both of A and B were replaced by perforated glazed socketed pipes surrounded by 6 inches of coarse clinker, while the surface of the bed was covered by 3 inches of fine material. The body of A was filled up with clinker which passed a ¾ inch mesh but was rejected by ⅛ inch mesh. Bed B was refilled with its old clinker, *i.e.*, clinker which passed a 1 inch mesh, but was rejected by ¼ inch mesh. Report.

Beds A and B, as they stand at present, therefore date from August 18th and 22nd, 1899; C and D from April 13th, 1899; and D (relaid) from May, 1900.

On February 16th, 1899, raw sewage was allowed to flow through a by-pass* into No. 1 precipitation tank (which has a capacity of 1,125,000 gallons), and it continued to do so with only a few interruptions of an hour or two's duration until May, 1900, *i.e.*, from 14–15 months, when the tank had to be cleaned out, being two-thirds full of sludge.† As a rule the flow through the tank was such that the water just passed over the sill at the north end in a very fine stream, and this was found on measurement to amount to 1,700,000 gallons per 24 hours. *The stay of the liquor in the tank was therefore about 16 hours.* The usual scum gradually formed until it covered the entire surface of the liquid. p. 36.

After April 27th, 1899 (*i.e.*, 2½ months after starting), the liquor from the open septic tank was led on to beds A and B. The first results were not quite satisfactory, partly owing to A being faulty, and to the fact that the beds had hitherto been accustomed to raw sewage. But generally speaking, the final effluent complied with the Mersey and Irwell standard. p. 37.

* It is to be noted that this by-pass is 1ft. 6in. above the invert of the sewer, the average depth of sewage in the pipe being three feet. Even allowing for the fact that the sewage, by the time it reaches Davyhulme, has travelled about six miles, and has therefore got well broken up, one would think that this 18in.-high outlet pipe would hardly deliver an average sample of the sewage into the tank. There would probably be less that a proportionate amount of the sediment withdrawn. The point is worth noting, because this would affect the time required for the silting up of the septic tank.

Since the foregoing paragraph was written, Mr. Frye has drawn samples of the crude sewage at different depths in the culvert, at a point about 80 yards above the inlet pipe to the open septic tank, and has analysed them with the following results:—

—	Bottom of Sewer.	Half way up (*i.e.* 1 ft. 6 in.)	Top of liquid in Sewer.
Parts per 100,000.			
Total suspended matter - - -	47·1	48·3	55·5
Consisting of:—			
Inorganic matter - - - -	14·3	14·2	14·2
Volatile „ - - - - -	32·8	34·2	41·3
	47·1	48·3	55·5

A great many such estimations would have to be made before any conclusions could be drawn with regard to this. But, contrary to what one would have expected, these analyses show no difference in the percentages of detritus at different depths in the sewer; the larger percentage of organic matter at the top of the liquid was due mainly to grease.

† It is stated in the Report (p. 36) that, up to October, 1899 (*i.e.*, after the tank had been eight months in use), "the only notable quantity of sludge which can be perceived, on dipping with a rod, is immediately beneath the inlet penstocks." But this was probably an under-estimate, for Mr. Frye has found at Leeds that thin sludge in a tank offers no apparent resistance to a rod. The subsequent rapid accumulation of sludge was no doubt partly due to 279 barrows of garbage, which were intentionally tipped in between October 4th and 31st, 1899, in order to see whether the tank was capable of dealing with more solid matter than it received in the course of the ordinary day's flow.

Report. On June 1st, 1899, the effluent from the open septic tank was treated on beds C and D, which, from the 13th of April previously, had only had two fillings per day of settled sewage. The results were excellent (*Table VIII.*) "Recently (*i.e.*, in the autumn, of 1899) it has been found possible to deal with 4 fillings per day, *every single sample of effluent being non-putrescible and well within the limit of impurity.* A large amount of nitrate nitrogen is present in every sample of the filtrate."

Table VI. (Report, p. 37) is of such importance that it is advisable to give it in full:—

"Table VI.

"Showing the quantity of effluent from *open septic tank* dealt with by double contact on beds C and D in gallons per day (depth of acre-bed taken at 3·3 feet).

Date, 1899.	Capacity of Bed C.	Quantity dealt with in gallons per acre per day.	Number of fillings per day.
June 1 - - - - -	3,690	316,203	2
June 8 - - - - -	3,690	474,304	3
July 6 - - - - -	3,690	632,405	4
August 17 - - -	3,250	742,616	8 on C {4 on B, 4 on D}
September 14 - -	2,000	456,994	" "
October 4 (after 18 days' rest) - - - -	3,320	758,610	{4 on C, 4 on A} 8 on D

p. 38. The analyses of the liquor from the open septic tank (*Report, p.* 38; *Table VII.*) showed it to be practically the same as that from the Cameron closed tank; and that it was very uniform throughout—and in this respect very different from the raw sewage—is seen from the following figures (*Suppl. p.* 10). These figures represent a series of hourly analyses, extending over a fortnight.

—	4 hours' Oxygen absorption.		Acidity (relative).	
	Max.	Min.	Max.	Min.
Sewage - -	22·0	3·0	5·20	0·15
Tank liquor -	9·0	4·0	1·00	0·40

(Cf. *also Table I. and Diagrams A to E.*)

p. 38. Page 38 of the Report is taken up with discussing the relative values, as shown by the results, of the Cameron Septic tank system, *i.e. closed tank and one filter-bed contact*, as against *open tank and two filter-bed contacts* (*Table VIII. and Diagrams* 13 *and* 14.) The conclusion at which the Experts arrive is that—

"When both systems are dealing with the same volume of sewage on the same area, the advantage as regards efficiency belongs most indisputably to the double-contact system. We would emphasize that our experiments clearly show that the key to efficiency in the bacterial treatment of sewage is multiple as opposed to single contact."

"We have further quite recently obtained results which indicate that a most important economy may, by suitable management, be effected in the area required for efficient bacterial treatment. Thus, we have found that by mixing the effluent from a first contact bed with that from a second, a liquid is obtained which withstands the incubator test, and which is incapable of putrefaction. *See Table IX.; also Diagrams* 15, 16 *and* 17.)

This is described as "The Method of 1½ Contacts." And, although it is not proposed to make the size of the filter beds conform to this scheme of treatment, the possibility of dealing with the open septic tank liquor in this manner, *if required*, allows for frequent resting of the filter beds and other contingencies.

Supplement p. 11 Again, "latterly it has been found, as the diagrams clearly show, that one contact is in general sufficient to secure adequate purification."

Rainfall at Manchester.

On pages 41-42 details are given of the rainfall at Manchester, and of the rates at which the rain falls. The authors conclude this section thus:—

"In our judgment it is of the utmost importance, as far as possible, in all contemplated works, that the rainfall should be separated where it conveniently can be from the sewers, and that no natural water courses should be conveyed into the sewers."

Experiments on Storm Water.

These experiments were begun on 25th March, 1899, and have been continued since, as opportunity has arisen. (*See Tables XI. and XII.*) They were first carried out in beds A, B, and D, while subsequently C was also worked in conjunction with D. The storm water was always passed first into the small settling tank (for what length of time is not stated), before admission to the beds.

On page 45 the authors summarize the results of those experiments, which they think are the first to have been systematically carried out with storm water, and from this summary a few points may be noted:—

"Detailed analyses of the sewage and estimations of suspended matters show that there is even a greater amount of oxidisable matter in the first flush (after a storm) than in ordinary sewage."

"It is evident that a distinction must be drawn between the first flush of a storm and the highly diluted sewage which follows, the latter alone being properly designated as storm water. . . . The 'first flush' lasts, in the case of Manchester, from two to four hours." (Cf. *Diagram* 20; *also Diagrams* 4 *to* 12.)

"After a heavy and long-continued rain, the sewage may become so dilute as to be within the Mersey and Irwell standard immediately after passing through the settling tanks. Such an effluent would not need to be treated, and consequently such a storm should afford a period of rest to the filtration area."

I should like to take this opportunity of pointing out that a filter effluent and a dilute storm sewage, each showing less than 0·1 part albuminoid ammonia and 1·0 part "oxygen absorbed" per gallon (M. and I. Standard), are very different things. Although I have not yet actually tested the point directly, I should expect (from many experiments on the aëration of effluents) a dilute storm-water sewage, showing 0·1 part albuminoid ammonia and 1·0 part "oxygen absorbed" per gallon, to putrefy on incubation—*i.e.*, to be unfit to run into a reservoir like the Manchester Ship Canal. (I shall investigate this point experimentally later.)* G.M.

A storm has the effect of cleansing the sewers. Hence for some time after a storm the results given by the filter beds are somewhat better than usual.

The authors draw the following conclusions from these storm-water experiments:—

"1. Provision must be made for the storage of the first flush of sewage** at the beginning of a storm.

"2. It is probable that accelerated treatment may be commenced about two hours after the augmented flow has begun to reach the works.

"3. Adequate purification of storm water (*i.e.*, purification such as will make the storm water effluent stand the incubator test) can be effected by short double contacts, or in the case of extreme dilution even by single contacts, the length of the cycle being inversely proportional to the flow of the sewage.

"4. When, after a storm, ordinary treatment is resumed, the beds have been proved by experiment to show no decrease in purifying efficiency."

* *Note.*—Since the foregoing was written, I have diluted a few sewages with tap water down to the M. and I. Standard of albuminoid ammonia (and to less than the proportionate figure for "oxygen absorbed" in most of the cases), and have found that they all became putrid upon incubation.—G. M. (May, 1902).

** Since the Report was published, I understand that the *separate treatment* of the first flush has been decided upon as being the best method, and so the question of storage falls aside.

G. M.

And again :—

"The problem of the treatment of storm water appears to resolve itself into providing a system of rapid treatment continued for a limited time.'

Experiments were therefore made to see whether a bed would effect purification if worked for a limited period in cycles of much shorter duration than the normal, an extended period of rest being afterwards allowed. The results of these experiments were satisfactory. Mr. Fowler comments on the point that a long rest means an increase of nitrate in a bed, and therefore a temporary augmentation of its purifying power.

Beneficial Effect of the Effluent on the Water of the Ship Canal.

A long series of determinations were made by the incubator test, to determine the effect of mixing one volume of Ship Canal water with one volume of a mixture of the four effluents obtained from beds B and D in the course of the day. The result was that the effluents clearly improved the quality of the Ship Canal water, the nitrate in the effluents exerting an oxidising action upon the impurities in the water.

It is not stated in the Report whether the above effluents from B and D underwent any aëration before being mixed. But, even if they did to some extent, I do not think this would appreciably detract from the value of the experiments.

G. M.

Volume and Character of the Manchester Trade Refuse.

This subject is reviewed and the following conclusion is arrived at :—

"The total quantity of prospective trade refuse from all sources does not amount to more than 10 per cent. of the total estimated future sewage flow. The effect of this trade refuse on the purification process is not therefore likely to be of a serious character."

In a list which is given in the Report, showing "the nature and volume of the trade effluents which may in future be admitted to the sewers" (a volume of 2,570,000 gallons is allowed for), no mention is made of iron liquor. If iron liquor is not to be allowed in, the life of the filters will be lengthened (see Appendices E and F). This section is not so clear as the rest of the Report, and it is not quite evident from it whether it is proposed to exclude any trade effluents from the sewers, and if so, which trade effluents.

Temperature of Sewage and Air.

Pages 51—52 of the Report give a number of readings of the temperature of sewage and air at different seasons of the year, as measured at Davyhulme. During the winter months the sewage was warmer by about 10° Fahr. than the air, the average temperatures of the sewage at the outfall, from December, 1898, to April 14th, 1899, being 55·9°, 52·9°, 54·6°, 57·9°, and 54·3° Fahr. From January 24th to February 6th, 1899, very cold weather was experienced, ice being formed on the experimental beds. But "on no occasion has any difficulty been experienced through the small layer of ice which has formed on the surface of the beds. The comparatively warm sewage at once melts the ice, and finds its way into the bed."

MANCHESTER EXPERTS' CONCLUSIONS AND RECOMMENDATIONS.

These are summed up on pp. 35-38 of the Report, and should be read as they stand.

SUPPLEMENTARY REPORT.

On 22nd December, 1899, *i.e.*, seven weeks after the issue of the foregoing Report, a Supplementary Report was issued confirming and extending the results previously obtained. This contains correspondence between the Manchester Rivers' Committee, the Experts, the Local Government Board and the Mersey and Irwell Joint Committee. The Experts adhere to their original recommendations.

Appendix B of the Supplement consists of a number of further interesting experimental results from Mr. Fowler, obtained down to 13th December, 1899; as before, these are illustrated by diagrams. Those dealing with tank sludge and suspended matter in septic tank liquor will be referred to in the last part of this critique. Supplement
Pages 13-16 are full of details of the methods of working the filter beds, so as to get at the most economical plan; *e.g.*, on page 15 it is mentioned that the effluent on the second-contact bed D was allowed to stream slowly through the bed all the time, with the object of saving labour. Pages 17-18 detail experiments on the mixing of the effluents from C and D (the mixed effluent being always kept up to the Mersey and Irwell standard, and also withstanding the incubator test), so as to economise filter-bed area. In conclusion, the following three paragraphs from Mr. Fowler may be quoted :—

"This result (obtained by the mixing effluents from C and D) is of great importance, as showing that only one-fifth of the total acreage (of the proposed new beds) need be at the lower level." p. 18.

"An area of 60 acres will give ample margin for one day's rest in seven, even when the average dry weather flow is taken at 30,000,000 gallons. The present average dry weather flow is found by measurement to be 26,300,000 gallons. A further margin is afforded by the 25 acres of storm beds, which will need to have at least two fillings per day put upon them, in order to maintain their efficiency."

"The above experiments all lead to the conclusion that, for economical treatment of sewage in bacteria beds, it will be found advisable to effect a high degree of purification in a certain portion of the sewage, and mix this (effluent) with another portion less effectively dealt with." p. 19.

The Manchester Reports thus prove quite clearly that from the time when *open septic tank liquor* came to be treated on the filter beds (or, at least shortly after that time), a satisfactory effluent was obtained. A reference to *Appendix A*, which gives the detailed analyses of a few samples drawn on December 5th, 1899, and January 3rd, 1900, shows that the final effluents at those dates were excellent. There was an unavoidable delay in the analysis of the second set of these samples, but this does not affect the general point. It would, of course, be foolish to draw any conclusions from one or two analyses; but, so far as these go, they corroborate the results in the Reports.

On page 8 of the foregoing summary, the comparative evenness in composition of the open tank liquor as compared with sewage, both with respect to "oxygen absorbed" and acidity or alkalinity, is noted. But it was thought advisable to further estimate the amount of organic matter (as measured by the *organic nitrogen*) which the tank liquor contains, and therefore seven further samples, drawn at different dates—most of them by Professor Boyce—were tested for this. The results are given in *Appendix B*. They substantiate the very even composition of the liquor, and also the fact that—fortunately for the Manchester filter-beds—the liquor is weak. *Broadly speaking, it does not contain more than four parts of total combined nitrogen per* 100,000, *two parts of this being organic nitrogen and two parts ammoniacal nitrogen.** The beds have thus a comparatively light task to perform, so far as the destruction of organic matter is concerned.†

The next point to consider was: Given this good effluent, at what cost to the tank and filter-beds was it being produced, *i.e.*, how quickly was the tank sludging up, and were the filter-beds being choked at all, and if so, with what kind of sludge ?

---

*Had the liquors been analysed immediately they were withdrawn from the tank, the ammoniacal nitrogen would have been somewhat less and the organic nitrogen correspondingly more than is shown by the actual figures in the appendix.

†Sewage from different places varies so greatly that it is rather hard to say how much organic nitrogen an average tank liquor would show. Probably three to four parts of organic nitrogen and three to four parts of ammoniacal nitrogen would not be far wrong.

Supplement.

p. 9.

1. Destruction of Sludge in the Open Septic Tank, and Sludging up of the Tank.

Mr. Fowler, I understand, calculates that the Manchester tank, in which the stay of the sewage has been only 16 to 11 hours, destroys about 30 per cent. of the original sewage sludge. Careful calculations on the same subject have also been made by the sewage authorities at Leeds, where twenty-four hours is allowed for the "septic" action, and where it is considered that nearly 50 per cent. of the total sludge is dissolved. But both Mr. Frye and I feel that this point—one of the most important of all as regards sewage treatment—requires further experimental investigation. No two sewage sludges are likely to dissolve in a tank to the same extent.

As already stated, the Manchester open tank was cleaned out in May of this year, being then two-thirds full of sludge. But the rate of the flow of the sewage through it had varied. For the first eight months it had been about 1,700,000 gallons per twenty-four hours (giving a stay of about *sixteen* hours in the tank); while on October 18th, 1899, the screen at the entrance to the by-pass from the main sewer was removed, causing a flow through the tank of 2,500,000 gallons in twenty-four hours (equal to a stay of *eleven* hours, in the tank). Then, from October 4th to 31st, 1899, 279 barrows of garbage (collected from the mechanical screens at the entrance to the works) were tipped into the tank, but this had to be stopped, as the destruction was not sufficiently rapid. Between October 31st and December 13th, however, it is stated that a very large portion of the garbage had disappeared, the disintegration of matches, paper, etc., being plainly visible.

Under these circumstances, combined with the fact that the tank received sewage from a by-pass which was 1ft. 6in. above the invert of the sewer, any detailed criticism as to the rate at which the tank would sludge up under normal conditions is hardly possible. So much suspended matter was latterly coming away in the tank liquor (and lodging on the first contact bed) as to show that the tank should have been cleaned out at an earlier date than it actually was.

p. 10. Mr. Fowler states that determinations of this suspended matter made on different days gave numbers ranging from 4·9 to 11·6 grains per gallon, of which 55 per cent. was mineral matter. He apparently argues that, since no permanent decrease in capacity has been observed for a long time in the Roscoe filters, which receive chemically-precipitated effluent containing 1·35 to 4·0 grains suspended matter (60 per cent. of which is mineral), the same thing would hold here. But I think this would be better for further proof, because of the iron in the open septic tank effluent.

The length of life of the open septic tank, there fore, under ordinary conditions has still to be demonstrated.

Appendix C gives the results of the analysis of a sample of the Manchester tank sludge made by Mr. Frye. It contains, as might be expected, more sand than the sludge from filter-bed C.

2. Were the Filter-Beds, Especially the First Contact Beds, Being Choked up at all, and, if so, with what?

The presumption is, of course, against any appreciable choking, at any rate, of the second contact beds, judging from the excellent quality of the effluents. But it was thought well:—

(*a*) To make a direct test of the aëration of the beds (I should mention here that the idea of extracting the gases from a filter bed was originally due to Professor Ramsay).

(*b*) To examine the material of the filter-beds for sludge.

(*a*) *Aëration of the Filter-Beds.*

Appendix D gives the results of a direct test of this, *i.e.*, it gives the analyses of eight samples of gas drawn from the interior of several of the filter-beds. Without going into minute detail, these analyses show that the beds (excepting the first contact beds A and C, on December 5th, 1899), down to the depths given, were very fairly aerated, *i.e.*, oxygenated, on the dates mentioned. The most striking difference is between the first contact bed A on December 5th, 1899, and the same bed on January 3rd, 1900; on the latter date its aëration was very much better. Between those two dates, however, bed A had had a week's rest, which doubtless accounts for the improvement observed.

(*b*) *Examination of the Filter-beds for Sludge.*

In Appendix E are to be found the analyses of four samples of filter-bed material (three from first contact bed C and one from Cameron bed No. 3), and also analyses of the fine mud which that filtering material now contained. It will be seen that the greater part of this mud was at the top of the bed, but that it was gradually finding its way through. In connection with E, Appendix F should also be read, which gives data on the amount of iron and the state of that iron in the sewage, open and closed septic tank liquors, and first and second contact bed effluents. The points that strike one most here are:—

1. The large amount of iron in the Manchester Sewage.

2. The very large amount in the open septic tank liquor before the tank was cleaned out (and the same applies to the closed Cameron tank still).

3. The fact that as much as 1·5 parts of iron per 100,000 were latterly coming through the first contact bed, while almost none escaped through the second contact bed.

4. The fact that the iron in a sewage (*i.e.*, tank liquor) settles relatively more slowly than the other solids.

It is, therefore, evident that this part of the Manchester inquiry is not yet completely solved. It looks as if either more tank accommodation were necessary, or some rough and easily renewable filter between the tank and the filter beds proper, so as to prevent any appreciable amount of iron—and, with this, fine grit—passing on to the first contact bed. By one of these means the "life" of the first contact beds would undoubtedly be greatly prolonged.

In conclusion, it may be well to sum up shortly the main points of this criticism:

1. That the Manchester experiments, so far as they have gone, are most valuable.

2. That, from a chemical point of view, an excellent effluent is produced; and that the presence of the very large quantity of tarry matter has, so far, had no prejudicial effect upon this.

3. That it might be desirable to have some further data as to the first contact beds maintaining an average capacity of one-third of the empty tank capacity.

4. That the freeing of the tank liquor from suspended matter, and from all but a small quantity of iron, has not yet been accomplished to the extent which is desirable. When this is done the "life" of the first contact beds will be much lengthened.

I cannot conclude this without expressing my thanks to Sir Bosdin Leech, the Chairman of the Rivers Committee, and Mr. Fowler, who have been kind enough to give every facility to Mr. Frye and myself in the course of this inquiry. And my hearty thanks are due to Mr. Frye for his work in connection with it. Nearly all the analyses relating to the iron and sludge were done by him, and he has also made many valuable suggestions, the substance of which is given in these pages. I should also add that the analyses of the tank liquors and effluents (Appendices A and B) were made by Mr. R. B. Floris.

Ealing, July 10th, 1900. *George McGowan.*

APPENDIX A.

	Corresponding Samples Drawn Tuesday, December 5th, 1899.		Corresponding Samples Drawn Wednesday, January 3rd, 1900.			Mersey and Irwell Standard.

Oxygen absorbed after 5 days Incubation.	—	—	3·09	0·24	0·05	—
	Slight earthy smell after incubation.	No smell after incubation.	Tarry smell after incubation.	Slight tarry smell after incubation.	Earthy smell after incubation.	
Chlorine	13·18	13·14	10·02	9·96	9·86	
Remarks	Two hours' contact. Liquid almost colourless, with copious green-brown flocculent deposit. Slight tarry odour; alkaline.	One hour s contact. Almost no suspended matters. Slightly opalescent. Earthy odour. Nearly neutral.	Considerable black sediment. The filtered liquor was slightly yellow. Tarry smell; alkaline.	This sample had 2¼ instead of 2 hours' contact. Clean and tarry odour. Copious green-brown flocculent deposit. Slightly acid from carbonic acid.	Fairly average sample. Bed running all the time. Clean and colourless, like tap water; contained a few tiny worms. Slightly alkaline.	
GASES.						
Cubic centimetres per litre at N.T.P.	*Note.*—It will be observed that in every *Effluent* there is a reserve of Nitrate.					
Carbon dioxide (free)	55·0	40·7	—	53·9	42·2	—
‡Oxygen	1·0	2·6	—	0·9	1·4	—
Nitrogen	17·7	16·2	—	19·6	18·3	—

* This bottle had been mercury-jointed since 4th January.

† This is probably an error in the analysis; there would almost certainly be some "X" nitrogen present in the tank liquor and a little in the effluents. (G. M., May, 1902.)

‡ *Note.*—These figures for the oxygen must be a little higher than the reality, owing to slight aëration while transferring the effluents into the gas apparatus.

APPENDIX B.

Ammoniacal and Organic Nitrogen in Manchester Open Septic Tank Liquor, 1900.

Sample drawn	March 16	March 21	March 23	March 29	April 5	April 20	June 15
„ analysed	„ 19	„ 23	„ 26	„ 30	„ 21 (This sample was delayed in transit.)	„ 23	„ 18
Parts per 100,000:							
Ammoniacal nitrogen	2·64	2·30	2·81	2·51	3·20	2·38	2·91
Organic nitrogen	1·67	1·81	1·29	1·88	0·89	2·37	0·69
Total Nitrogen	4·31	4·11	4·10	4·39	4·09	4·75	3·60

All the above samples had a strong tarry smell, and the first six of them showed a considerable black deposit containing iron. Between the drawing of the sixth and seventh samples the tank was cleaned out, and the last sample had very little deposit.

APPENDIX C.

Analysis of Manchester Open Septic Tank Sludge.

This (average) sample was drawn when the tank was being cleaned out in May 1900, after fully fourteen months' use. At the inlet end the sludge was of a brownish colour, and very solid, but at the other end thin and quite black. It contained both animal and vegetable fibre, and smelt strongly of waste coal-tar products. The following figures were obtained :—

—	—	Calculated for the dry sludge.
	Per cent.	Per cent.
Moisture	81·00*	—
Matter volatile above 110° C.	6·98	36·7
Non-volatile matter, insoluble in hydrochloric acid	4·90	25·8 } = 45·1
Non-volatile matter (other than iron), soluble in hydrochloric acid	3·67	19·3 }
Iron (calculated as melallic iron)	3·00	15·8
Sulphur present as sulphate	Trace.	Trace.
Sulphur present as sulphide	0·45	2·4
	100·0	100·0

* *Note.*—The iron was, of course, not present as metallic iron, but as sulphide and hydroxide. Hence the figure given for either the moisture or volatile matter is not absolutely correct.

APPENDIX D.

ANALYSES of GASES drawn from the interior of the Manchester Filter Beds.

Samples 1, 2, 3, and 4 were drawn on 5th December, 1899 ; 5, 6, 7 and 8 on 3rd January, 1900.

—	Atmospheric Air.	No. 1. From 1st Contact Bed A, about middle of Bed, and at a depth of 2 feet. Bed had rested 3¼ hours (usual rest is 3 hours).	No. 2. From 1st Contact Bed C, about middle of Bed, and at a depth of 2 feet. Bed had rested 50 minutes (usual rest is 1 hour).	No. 7. From 1st Contact Bed A. From upper end of Bed and about half way across it, at a depth of 2 feet. Bed had rested 3 hours (the usual time before refilling).	No 8. From 1st Contact Bed A. From lower end of Bed and about half way across it, at a depth of 2 feet. Bed had rested 3¼ (instead of 3 hours).	No. 4. From 2nd Contact Bed. From middle of Bed, at a depth of 2 feet. Bed had rested 1 hour (the usual time)	No. 5. From 2nd Contact Bed D. About 1-3rd down the Bed and 2-3rds across it, at a depth of 1 foot 4 inches approximately. Bed was still running. It was about to be refilled.	No. 6. From 2nd Contact Bed D. Near lower end of Bed and about half way across it, at a depth of 1 foot 4 inches approximately. Bed running as above.	No. 3 From Roscoe Bed (cinder). From about middle of Bed at a depth of 2½ feet. Bed had rested 3 hours (2 hours is the usual time).
By Volume.

APPENDIX E.

STATE OF THE MANCHESTER FILTER BEDS AS REGARDS SLUDGE.

The bed which has been mainly examined is the *First Contact Bed C.* This, it will be remembered, dates from April 13th, 1899.

—	Bed C. (1). Sample drawn by Mr. Fowler 3 inches below surface, about middle of bed, on March 21st, 1900. The bed had been run off for four hours.	Bed C. (2). Sample drawn under same conditions as (1), but 1 foot below surface.	Bed C. (3). Sample drawn by Mr. Frye on April 20th, 4 inches from the bottom. The bed had been resting for a week. *This had a sewage smell.*	Cameron Bed No. 3. (4). An average sample drawn by Mr. Frye on April 20th. This smelt of Nitro-benzene.
Moisture - - - -	28·20	27·20	37·30	41·00
*Fine Mud - - -	10·05 (by dif.)	4·40 (directly)	3·30 (directly)	3·33 (directly)
Clinker and coarse Sand	61·70	68·32	58·81	55·65
Sulphur as Sulphide -	Trace.	Trace.	Trace.	—
Total Sulphur - -	0·05	0·08	0·09	0·02
	100·0	100·0	100·0	100·0

* *Analysis of the above dried muds.*—These muds were obtained by gently and repeatedly stirring up the clinker with small quantities of water in a mortar, until the liquid ran off clear, or nearly so.

					Tank Sludge.
Volatile matter - -	45·10	45·40	45·20	44·50	40·6
†Iron, calculated as Sesquioxide - - -	24·71	24·20	18·80	23·40	22·60
Sand, etc. (by dif.) - -	30·19	30·40	36·00	32·10	36·80
	100·0	100·0	100·0	100·0	100·0

† Ten parts of sesquioxide of iron are equivalent to 7 of metallic iron. The iron was no doubt present for the most parts in a less oxidized from than the sesquioxide ; the amounts of "sand, etc." as given above, are therefore below their true value.

APPENDIX F.

IRON in the MANCHESTER SEWAGE, Open Septic Tank liquor and Filter-bed effluents at different dates.

SERIES I.

OPEN SEPTIC TANK LIQUOR.

Parts per 100,000.	1900. March 23.	March 21 and 29 (mixed).	June 15.
Fine Grit	4·0	2·82	1·21
Iron in colloïdal and true solution, given as metallic iron	1·33	6·58	1·64
Iron in suspension	5·81		

Notes.—1. The "iron" also includes any alumina present.

2. Between March 29th and June 15th the tank had been cleaned out, and the difference in the figures for iron is at once apparent. The difference in the appearance of the samples was equally marked; the earlier ones contained much black iron sediment, whereas in the sample of June 15th there was hardly any.

SERIES 2, 3, AND 4.

When the samples of Series 2 were drawn by Mr. Frye, the open tank was being cleaned out. Hence a sample of liquor from the *closed* Cameron tank was taken instead.

The "iron" in these series does *not* include any alumina present.

Parts per 100,000.	Sewage.	Open tank.	Closed Cameron tank.	Effluent from Bed C.	Effluent from Bed D.
(2.) 9th May.					
Iron in suspension	0·56	—	4·16	0·40	0·12
Iron in colloïdal and true solution	0·34	—	0·84	Trace	Faint trace.
	0·90	—	5·00	0·40	0·12
The open septic tank had now been re-started for 3½ weeks, but it was not yet properly septic.					
(3.) 11th June.					
Iron in suspension	13·42	0·68	2·44	0·46	0·05
Iron in colloïdal solution	0·46	0·46	0·76	Trace	Trace
Iron in true solution	0·12	0·06			
	14 00	1·20	3·20	0·46	0·05
There had obviously just been a heavy flush of iron liquor into the sewage.					
(4.) 15th June.					
Iron in suspension	2·54	0·46	9·20	1·32	0·10
Iron in colloïdal solution	0·26	0·81	0.80	0·12	—
Iron in true solution	Trace	0·03	Trace	—	—
	2·80	1·30	10·00	1·44	0·10

There had been rain just before these last samples (Series 4) were drawn, and the sewage was at nearly twice its normal flow. For this reason the iron in the sewage is probably only half what it would have been normally. The other samples are not affected by this.

SERIES 5.

(a). *Manchester Sewage. Average sample of six days*, taken every hour from June 11th, 1900, 9 a.m., to June 17th, 6 a.m.

(b). *Open Tank Liquor. Average sample of six days*, taken exactly like the sewage above. [N.B.—The tank was not yet properly septic.]

(c). *Average sample* of all the emptyings from *First Contact Bed C* on June 14th, 15th and 16th (*i.e.*, throughout three days). Samples were in this case taken every five minutes while the bed was being emptied.

(d). *Average sample* of all the emptyings from *Second Contact Bed D*, taken for three days in exactly the same way.

Parts per 100,000.	Sewage.		Open Tank Liquor.		Effluent from Bed C.		Effluent from Bed D.	
	Grav.	Vol.	Grav.	Vol.	Grav.	Vol.	Grav.	Vol.

Solids in Suspension	61·5		7·52		3·20		2·50	
Solids in Solution	75·5		76·88		77·20		79·92	

NOTES.—1. These average samples were taken in equal quantities, not according to rate of flow; but the results given by Mr. Fowler in Annual Report for the year ending March 27th, 1901, p. 33, show that the difference between the samples taken in this way and others taken according to the rate of flow is not very striking, at any rate in dry weather (May, 1902).

2. The volumetric estimation gives the iron proper. The difference between the gravimetric and volumetric gives the alumina, calculated as iron.

3. When the samples from Beds C and D were taken, the beds had only been working for a week, since resting for a fortnight, and one foot of material had been removed from Bed D during the rest. The depth of material in D was therefore two feet.

4. The amount of iron in the Manchester sewage is much greater than we had supposed.

The mud (under the microscope) was seen to be composed of very small particles. It contained some fibre, but not anything like so much as Mr. Frye finds in the mud of the Leeds beds, which are treating crude sewage there. The chief differences between the Manchester and Leeds filter-bed muds are:—

MANCHESTER.	LEEDS.
Chocolate brown.	Reddish brown.
Finely divided.	Pulpy.
Slightly fibrous.	Very fibrous.

Further, on drying, the Leeds mud shrank considerably, and could be shaken off the coke, whereas the Manchester mud adhered to the clinker so strongly that it could only be got off by boiling water and rubbing. The Manchester sludge was the more easily washed off when wet.

It will be seen from the above figures that the percentages both of fine black mud and of iron got less, the deeper down in the bed the samples were drawn. At the bottom of the bed C, on April 20th, the clinker smelt very badly. This, I think, shows that the bed was not in a satisfactory condition at that date, although it had rested for a week. The upper samples had only an earthy smell.

All the above "muds" agree very nearly in composition, and, as Mr. Frye has already pointed out, this looks as if the organic matter of the mud was broken down nearly as far as it could be under actual working conditions. The same thing is noticeable in the muds from the Leeds beds, *i.e.*, they agree in composition among each other, but in these the percentage of volatile matter is higher than in the Manchester samples (about 55 per cent. as against 45 per cent.). Another point of interest is that the Leeds Whittaker bed mud contained far more sulphide than the Manchester samples; Mr. Frye finds that, the greater the amount of sulphide, the more clogged this particular bed appears to be.

A short examination of the foregoing figures in this appendix shows:—

1. The very large quantity of iron that was being brought over by the tank liquor on to the first contact bed, before the tank was cleaned out.

2. The larger quantity of fine grit that was also being carried over under these circumstances.

3. That the liquor from the closed Cameron tank is also delivering much suspended iron, and requires to be cleaned out. Besides the iron in suspension, there is also more iron in solution in the closed tank liquor than in the sewage.

4. That the average six days' sample of sewage is very heavy both in iron and suspended matter.

5. That when one compares the open tank liquor (six days' sample) with the sewage (six days' sample), the decrease in the iron is from 100 to 17·6 Grav. or to 21·9 Vol.,* while the decrease in suspended solids is from 100 to 12·2.

The iron therefore does not deposit so rapidly as the other solids. Mr. Frye has found exactly the same thing at Leeds.

6. That the two filter-beds C and D remove practically all the iron that is in solution in the liquid going on to them; and, by the time the final effluent has left the second contact bed, something over 90 per cent. of the total iron of the sewage has been removed (by tank and beds together). Further, the iron that is left in the effluent is practically all in suspension. This result in quite in agreement with those which Mr. Frye has obtained in the same manner from the contact beds at Leeds.

George McGowan.

Ealing, London, W.
July, 1900.

* *Note.*—The gravimetric estimation gives oxide of iron, alumina and alkaline earth phosphates together, while the volumetric gives iron alone.

PROVISIONAL NOTE ON THE BACTERIOLOGICAL QUALITIES OF CRUDE SEWAGE AND SEWAGE EFFLUENTS AND THE QUESTION OF STANDARDS IN RELATION TO POTABLE AND NON-POTABLE STREAMS.

Dr. Houston.

THE BACTERIOLOGY OF CRUDE SEWAGE.

Total Numbers.

Crude sewage usually contains at least one million bacteria per cc., and not uncommonly more than ten million. Of these a large proportion are capable of growing in the laboratory at blood heat.

But as this proportion of the several sorts of sewage microbes which together go to make up the total number of bacteria in a sample does not necessarily remain constant throughout the complex changes leading to the ultimate purification of the sewage, only a limited amount of reliance can be placed on estimation of total numbers. For example, different processes of sewage disposal, all yielding fairly comparable results as regards the total number of bacteria in their respective effluents, may yet differ one from another in marked fashion in respect of the sorts or kinds of bacteria (and their relative abundance) which together went to make up the total number in each of the several effluents.

B. Coli.

The number of B. Coli (or closely allied forms) in crude sewage is apt to be at least 100,000 per cc. B. Coli is an intestinal bacterium, which may be pathogenic, and certainly its presence serves as an index of the probable presence of other and perhaps more objectionable bacteria of excremental sort. Hence enumeration of B. Coli in crude sewage and effluents may be considered highly important. If B. Coli is present habitually in from $\frac{1}{10,000}$ to $\frac{1}{100,000}$ of a cc. of raw sewage, and is absent, as has been alleged, in the bacteriological contents of as much, it may be, as 10 to 100 cc. of a pure water, this biological test is one of extreme delicacy. In connection with this test, as also with others, it is important to determine the number of such organisms per cc. A mere statement of their presence or absence is of little value.

Apart from the proof of its direct association with human ailments, any microbe pathogenic to the lower animals must be regarded with some suspicion as a possible cause of harm also to the human subject. But the more highly specialised forms of the Coli group would seem to be connected—in some cases obscurely, in others in more certain fashion—with the occurrence of definite morbid processes in man.

In brief, this B. Coli test must be regarded as of great importance: in the first place, because the presence of B. Coli serves as an index of the possible presence in the medium yielding it of other and more objectionable microbes; secondly, because certain strains of B. coli are distinctly pathogenic in the case of lower animals; and last, but not least because there is ground for considering that B. Coli may play a rôle in the causation of human diseases.

B. Enteritidis Sporogenes (Klein).

The number of spores of B. Enteritidis Sporogenes in crude sewage is usually at least 100 per cc. Avoiding matters which may be open to controversy, it is at the least certain that cultures of B. Enteritidis Sporogenes may be, and often are, extremely virulent to guinea-pigs. Further, there is evidence, according to Dr. Klein, that B. Enteritidis Sporogenes has been casually related to certain epidemics of acute diarrhœa in the human subject.

This B. Enteritidis Sporogenes test is one of easy application, and gives some indication of the total number of spores of anaerobic bacteria of all sorts present in the substance under examination. The B. Coli test is performed under aerobic conditions, and the B. Enteritidis under anaerobic conditions. *It seems most important to have an anaerobic as well as an aerobic test, and for this reason alone the continued use as a routine measure of the B. Enteritidis test is desirable.* The fact of its being a sporing anaerobe weakens somewhat the usefulness of the test as an indication of recent contamination in connection with the bacteriological examination of potable waters. But such an objection, for manifest reasons, does not apply to sewage effluents.

Incidentally it is of interest to note that the spores of B. Enteritidis are absent from as much as 100-500 cc. of a pure water, are present only in sparse numbers in virgin soils, but are present in great abundance in soils polluted with matters of excremental sort.

Streptococci.

The number of streptococci in crude sewage would seem to be at least 1,000 per cc.

Speaking of streptococci as a class, without special reference for the moment to sewage streptococci, it would appear that:—

They are delicate micro-organisms, and readily lose their vitality and die.

They probably are little prone to enter on a saprophytic phase or to multiply to any great extent, if at all, under such conditions.

They are present in the intestinal discharge of animals.

They comprise micro-organisms of highly pathogenic sort.

They are seemingly absent from relatively large amounts of pure waters and from virgin soils, but can be readily demonstrated in soils and waters recently polluted with excremental matters.

Assuming the foregoing to be even approximately true, this streptococcus test is an important one. For example, if the streptococci met with in sewage are of intestinal origin, and are of feeble vitality, their presence in any number in an effluent would lead to the inference that the "biological treatment" processes at work and responsible, as it were, for the production of such an effluent were not strongly inimical to the vitality of other and more hardy germs likewise of intestinal outcome. And in the latter category we would presumably be forced to include both the typhoid bacillus and the cholera vibrio. Quite the same could not be claimed for the Coli test already referred to since B. Coli is a more hardy germ than B. typhosus or the cholera vibrio. And it is worthy of note that this streptococcus test could be applied with confidence to any effluent from any system of sewage disposal, whereas search for B. typhosus in sewage and sewage effluents must be regarded as an almost hopeless task, and the failure to demonstrate its presence no indication whatever of its real absence. Recently, however, Dr. MacConkey has carried out an elaborate research, having for its main object the discovery of a simple and reliable method of isolating the typhoid bacillus from a liquid containing a mixed bacterial flora. Such a method would be of great value.

The pathogenicity of sewage streptococci does not appear to have been established, but it is well known that virulent streptococci rapidly lose their pathogenic action when separated from the animal body and cultivated on artificial media. Moreover, the failure to induce a pathogenic effect by the micro-organisms in the lower animals affords no sufficient criterion that the streptococci in question are harmless to man.

But putting aside the question of pathogenicity, the test in its positive aspects must be regarded as an index of no mean value of the probable biological quality of a sewage effluent in relation to the possible spread of disease.

Gas Test for Indicating Presence of B. Coli, B. Proteus, and other Gas-forming Bacteria.

The aerobic (or facultative anaerobic) gas-forming bacteria in sewage belong chiefly to the objectionable Coli and Proteus class, and a simple method of arriving at a rough estimation of the abundance of these microbes has been worked out. For example, $\frac{1}{1,000}$ cc. of crude sewage usually produces "gas" in gelatine shake culture in 24 hours at 20°C., while the bacterial contents of as much it may be as 100cc. of a pure water fail to effect a similar result.

This represents a remarkable biological distinction between raw sewage and pure water; and if, as seems likely, it can be shown that at any point between these two extremes the number of gas-forming bacteria affords a reliable index of the status of a liquid in respect of the degree of purification effected and its relative harmlessness, the test is a valuable one. Indeed, if there exists a parallelism between the number of gas-forming bacteria and the putrescibility and harmfulness of effluents, it might even be claimed that this test is of singular importance.

It would seem that no liquid containing these gas-forming bacteria in a minimal quantity can be considered free from the putrescible organic matter which maintains their existence. Theoretically this may be true, but practically the reduction of the putrescible organic matter might in some cases be so rapid as perhaps not to allow of a corresponding reduction in the number of these microbes.

Inoculation.

The injection subcutaneously of crude sewage even in moderate quantity into rodent animals, is always followed by a local reaction, and not uncommonly leads to a fatal result. Certain microbes isolated from the blood or tissues of such affected animal appear to be highly virulent. How far this is due to an exaltation of virulence of sewage bacteria due to their passage through the animal, and how far it is a virulence proper, as it were, to the microbes previous to the inoculation, may be hard to determine. And it seems doubtful if these peccant microbes could readily be recognised in cultivations made directly from the sewage without resorting to the inoculation of animals. Nevertheless, it is of considerable interest to learn that even small quantities of crude sewage habitually contain germs of a sort virulent to rodents. As a routine test, however, the inoculation of animals could hardly be recommended.

Other Tests.*

The enumeration of thermophilic bacteria, liquefying microbes, spores of aerobic bacteria, etc., although doubtless yielding results of considerable value, would seem to be of secondary importance to the tests already considered.

In summary at this stage we note that crude sewage usually contains at least in 1 cc.:—

1-10 million bacteria.

100,000 B. Coli (or closely allied forms).

100 spores of B. Enteritidis Sporogenes.

1,000 streptococci.

Further, that so minute a quantity as $\frac{1}{1,000}$ of a cc. of crude sewage is usually sufficient to produce "gas" in gelatine shake cultures in 24 hours at 20°C., and that the inoculation of animals with crude sewage always lead to a local reaction, and not uncommonly results in death.

THE BACTERIOLOGY OF SEWAGE EFFLUENTS.

A large amount of information has been gained under this heading. The general outcome of the experiments may be summed up as follows:—

Effluents from Artificial Processes.

The effluents from septic tanks, intermittent contact beds, continuous filtration beds, etc., contain an enormous number of bacteria. In some cases the percentage reduction of microbes in effluent as compared with raw sewage is striking. But as an effluent must be judged by the actual state it is in, and as the number of micro-organisms still remaining is nearly always very large, percentage purification would seem to be of minor importance. In not a few cases the bacteria are practically as numerous in the effluent as in the raw sewage.

The different kinds of bacteria and their relative abundance appear to be very much the same in the effluents as in the crude sewage.† Thus, as regards undesirable bacteria, the effluents frequently contain nearly as many B. Coli, proteus-like germs, spores of B. Enteritidis Sporogenes and streptococci, as crude sewage. In no case, seemingly, has the reduction of these objectionable bacteria been so marked as to be very material from the point of view of the epidemiologist. No definite proof has been furnished that the effluents from bacteria beds are conspicuously more safe in this sense in their possible relation to disease than is crude sewage. Indeed, all the available evidence tends to show that they must be regarded as nearly, if not quite, as dangerous to health as raw sewage. In this connection we would again take note of the streptococcus test. If it be true that streptococci are more delicate germs than the typhoid bacillus, their presence in any number in the effluent would seem to indicate the possibility or probability of the enteric fever bacillus also surviving under similar conditions, and, in general, would lead us to infer that the biological processes at work were not strongly inimical, if hostile at all, to the vitality of germs of pathogenic sort.

The inoculation of animals with the effluents from bacterial beds seems to show that they are nearly as pathogenic as crude sewage.

In conclusion, and speaking in general terms, it is to be inferred that the effluents from bacteria beds are bacteriologically so impure that they may well be excluded from streams that are used for drinking purposes. Need for this inference is the more to be regretted since the same effluents often pass a reasonable chemical standard. Presumably the bacteria-bed-process is so rapid that the decline in the amount of oxidisable and putrescible matter in the sewage passing through is not accompanied by a corresponding reduction in the number of bacteria; and commonly the units of material composing the bed are of so large a size as to preclude the possibility of the mere mechanical separation of the germs.

Effluents from Land Treatment.

Much work has been carried out as regards the bacteriological examination of land effluents, and the work is sufficiently advanced to call for a complete report within the next few months. In the meantime, some remarks on this subject of a provisional and general character seem advisable.

It would appear to be possible with land of proper quality, and, by intelligent management, to obtain remarkably good bacteriological results; in some, although rare, cases, results so good that, apart from a knowledge of its source, the effluent might actually be regarded as a potable water of more than average purity. Generally speaking, however, the effluents from land, like those from bacterial beds, are not to be thought of as in a fit state to be turned into a potable stream. Unfortunately also, the ratios one to another of the different sewage microbes tend to remain fairly constant, no matter how great the purification may be. The bacteria proper, peculiar, as it were, to the soil, are seemingly either absent or present in small proportion only in these land effluents. Yet the sewage bacteria do not seem to destroy the soil microbes; for examination of the soil itself shows that the latter are present in abundance. On the other hand, when the soil is "rested," some, at all events, of the sewage bacteria disappear. A broad parallelism would seem to exist between the chemical and bacteriological results obtained by land treatment of sewage. We may reasonably consider that this is due to the comparative slowness of the process allowing the bacteria in the sewage to decline in numbers side by side with the reduction in the amount of oxidisable and putrescible matter; and in this respect land treatment would seem preferable to artificial filters. At the same time, it must be remembered that the diminution in the number of bacteria by land treatment must also be traced to their mechanical separation. The effluents from land usually contain B. Coli, spores of B. Enteritidis Sporogenes, and even streptococci.

In conclusion, the treatment of sewage on land, although perhaps more satisfactory from the bacteriological point of view than its treatment in bacterial beds, would not seem to by any means entirely remove the danger arising from the discharge of effluents into potable rivers.

In general summary it is to be noted that the effluents alike from land and from bacteria beds contain B. Coli, B. Enteritidis Sporogenes, and Streptococci often in

* Since writing this report (Feb., 1901) other tests have sprung into prominence, notably, Dr. MacConkey's useful bile-salt broth test. These will be dealt with in a separate report.

† That, however, some selective process is really in operation need hardly be doubted, although it might require special media and special processes to prove it.

abundance, and that, therefore, they are not so modified bacteriologically as to allow of their safe introduction into potable rivers.

EFFLUENTS FROM CHEMICAL PROCESSES.

It may be seriously questioned whether we have sufficient knowledge as to the effect of the chemical treatment of sewage as regards the biological composition of the resulting effluents. We gather that chemical treatment of a sewage does not prevent further treatment of it in bacteria beds and on land, and in general does not destroy the sewage bacteria. But our knowledge is deficient in this respect, and much work must be carried out before conclusions of any value can be drawn. It is an important matter, because it might, for instance, be affirmed that a particular process—say a combined chemical and land, or a combined chemical and bacteria bed method—was satisfactory, because the chemicals first destroyed the pathogenic germs, while the land or bacterial beds afterwards purified the sewage, so that the final effluent was quite innocuous.

In this connection the streptococcus and B. Coli tests would seem, the former in its positive aspects, the latter in a negative sense, to be of value. For, assuming it to be true that streptococci are less and B. Coli more hardy than such pathogenic germs as B. typhosus and the cholera vibrio, the presence of streptococci would seem to imply the possible presence as well of disease germs, while the absence of B. Coli would suggest comparative safety?

THE CHEMICAL AND BACTERIOLOGICAL EXAMINATION OF EFFLUENTS, AND THE QUESTION OF STANDARDS IN RELATION TO DRINKING AND NON-DRINKING STREAMS.

It seems quite clear that a chemical examination of effluents will be required in the case of both potable and non-potable rivers. In both cases it is necessary to prevent the discharge into the river of an undue amount of oxidisable and putrescible matter. Even if an effluent were sterilised, a chemical examination would still be required to show that it contained no organic substance susceptible to the action of putrefactive bacteria present in the water of the river. Cases have occurred where an effluent rich in putrescible matter has been actually sterilised but which nevertheless produced a filthy nuisance in the river some distance below the point of discharge. The time is past to usefully discuss whether it is better to have a sterile effluent rich in organic matter, or a non-sterile effluent free, or nearly so, from putrescible matter. All effluents, whether sterile or non-sterile, must be relatively free from all substances susceptible to the action of putrefactive bacteria. Further, at all events in the case of drinking water streams, it is necessary for the chemist to say whether the effluent is free from chemical poisons in dangerous amount.

DRINKING WATER STREAMS.

Passing next to the more difficult subject of bacteriological standards, a bacteriological standard in the case of drinking water streams is certainly called for, and, indeed, is far more important than the chemical one. Yet, for the reasons above stated, a chemical standard must be retained as well.

Organic matter *per se* in water is seemingly harmless; it is the bacteria likely to be associated with the organic matter that constitute the element of danger. Only bacterioscopic analysis can hope to reveal the kinds of bacteria in an effluent which are of a sort liable to be related to disease. Chemistry is quite powerless in this respect, and, indeed, all chemical standards of potability are apparently based on an assumed relationship, which may or may not exist, between the amount of organic matter and the number and kinds of the associated bacteria. Typhoid fever stools, whether sterilised and innocuous, or unsterilised and highly dangerous, would yield to chemical testing practically the same results as regards the nature and amount of organic matter present.

Nevertheless, it may be doubted whether bacteriologists in general have fully met their responsibilities in this connection. For while it may be recognised that the burden of showing that an effluent is harmful or harmless (in the case of potable streams) ought to rest in their hands, the present state of bacteriological knowledge may not allow of their accepting the responsibility. It is one thing to believe in the principle of a bacteriological standard, and quite another thing to produce a standard which is altogether satisfactory.

But within recent years bacteriology has made great strides, and in directions tending to advance knowledge in this matter. For example, it would seem that bacteriologists have passed through a stage of mere enumeration of total numbers of micro organisms to a stage taking note of particular microbes; and from this have reached the stage of seeking to determine the relative abundance of these particular microbes in one or another substance. One result of these labours has been to show that a remarkable distinction can be drawn between pure water and a foul liquid like sewage, and that a water containing an amount of sewage so minute as to be beyond the reach of chemical analysis can yet be shown bacteriologically to be rich in intestinal microbes. A single instance will suffice: B. Coli is absent from as much it may be as 100cc. of a pure water, and yet is habitually present in from 1-10,000 to 1-100,000 of a cc. of crude sewage. On the plea of mere ability to recognise the presence and relative abundance of such intestinal microbes as may be considered to serve as in index of the possible presence as well of the bacteria of epidemic disease, the bacteriologist might reasonably claim that his delicate processes were in advance of the chemist. And this perhaps is as far as we may hope to get. For at present, when dealing with non-sterile effluents, the bacteriologist has no infallible test enabling him to say—this effluent does not contain the specific germs of epidemic disease. And we know that when these pathogenic germs are really present they may readily escape recognition.

But it would be unwise to regard sewage otherwise than as a liquid always potentially dangerous, and much is now known about its biological composition and the relative abundance of those intestinal germs apt to be associated with the pathogenic microbes which by their occasional or constant presence may render the liquid actually dangerous. By so much then as an effluent is modified in greater or less degree in the direction of departure from our normal sewage standard as regards these "germs of indication," to an equal extent are we privileged in measuring its status in respect of possible danger to health. In this sense bacteriologists have made real progress, and from this point of view standards may be of singular value.

The "microbes of indication" as has been already indicated would seem to be B. Coli, streptococci, and B. Enteritidis Sporogenes. These bacteria are wholly, or at all events relatively, absent from pure water; but there can be little doubt that some drinking waters do contain these objectionable microbes, although in insignificant proportion as compared with sewage and sewage effluents. Doubtless these waters are slightly polluted; but the fact of the presence in the water of these bacteria, and that they are used for potable purposes must not be lost sight of. Although on scientific grounds the complete removal or destruction of these bacteria is strongly indicated, it may be doubted if this counsel of perfection is wholly defensible in practice.

At this point it may be useful to consider ways and means of rendering a potentially dangerous effluent actually or relatively innocuous. Filtration might perhaps be employed to greatly and perhaps sufficiently reduce the number of bacteria present in an effluent. But it is open to doubt if the cost could be borne of first purifying sewage so as to get rid of most of the organic matter and the bulk of the suspended matter, and afterwards to subject the effluent to an efficient process of filtration. Presumably it would cost as much to satisfactorily filter the sewage effluent of a town as it would cost to filter the water supply of the same town.

Next as regards the complete or partial sterilisation of the effluents by chemical substances. By complete sterilisation is meant the absolute destruction of all microbes, sporing and non-sporing. By partial sterilisation the death of all bacteria present as bacilli (or in coccus form) is implied, but not the death of the spores of bacteria. And for a reason presently to be explained it is of advantage to limit this a little further by saying that this partial sterilisation may be judged to be sufficient if B. Coli is destroyed.

This distinction is important, because the difficulty of killing spores is very great, whereas bacilli (and cocci) are much more easily destroyed. Thus the thermal death point of B. Coli is about 60-65° C.; of some spores actually 120° C. And the same striking difference holds good in the main as regards chemical antiseptic substances. It is evident then that the difference in cost between the complete and partial

sterilisation of an effluent would be a very material difference, and it may be questioned if the additional freedom from danger resulting from complete sterilisation would merit the extra expenditure.

The number of spores of aerobic and anaerobic bacteria in sewage would seem to be about 100-1,000 per cc. in the case of a total bacterial flora of 1-10 million or more. So that the spores form a relatively small proportion of the total germs in sewage. Of pathogenic spores habitually or occasionally present in sewage B. Enteritidis Sporogenes, tetanus, malignant œdema and anthrax must be considered. Are we to consider that the risk of these and other sewage spores remaining in an effluent which is being discharged into a potable river is so grave that complete sterilisation is absolutely necessary? In the present state of knowledge this can hardly be said, and having regard to the almost insuperable difficulties attending complete sterilisation of effluents, to insist upon it would seem to be impracticable.

What then would the partial sterilisation of effluents mean? It seems justifiable to conclude that the destruction of B. Coli would mean the death of the typhoid bacillus, and perhaps in general of the germs of epidemic disease. And it may be seriously questioned if the practical difficulties and the cost of such partial sterilisation is in any way out of proportion to the enormous gain in securing comparative immunity from danger. A large number of substances would seem to be capable of effecting this object at a reasonable cost, *e.g.*, ozone and chlorine compounds.

The question what means are available for sterilising or partially sterilising sewage effluents, and what would be the cost of adopting such means, is one which should, I think, be definitely settled by further experiments.

In the present state of knowledge, and bearing in mind what is practicable, I consider that in the case of potable rivers it would be reasonable to require that an effluent be free, or nearly so, from putrescible matter as judged by chemical standards; and be free also from the specific germs of epidemic disease, *e.g.*, B. typhosus as judged indirectly but seemingly in safe fashion by the absence of B. Coli. It might be convenient to fix some limit, *e.g.*, that B. Coli must be absent from 1 cc. of a sewage effluent that if this end could be attained by filtration or other method not to consider the use of chemical substances essential. Nevertheless even sand filtration could not render an effluent innocuous in the same way as sterilisation. Such a standard as that suggested has the advantage of extreme simplicity, and it would take no note of the relative volumes of the effluent and river water, a matter which if taken into consideration greatly complicates the question of standards.

Non-Drinking Water Streams.

As regards non-drinking water streams the question of bacteriological standards is also a difficult one.

We must consider in the first place the possibility of the discharge of a bacterially impure effluent into non-drinking water streams being a means of spreading disease.

All streams which are not brackish or obviously offensive to taste or smell, or which do not present strongly to the eye the appearance of pollution, are liable to be used as sources of drinking water occasionally or even habitually by some individuals.

Bathing is commonly indulged in in non-drinking water streams. Whatever may be said of its comparative harmlessness, numerous cases of sickness and diarrhœa have been referred to this cause. And it would of course be quite possible for typhoid fever and cholera to be spread in this way.

Further, there is always the possibility of the water of non-drinking water streams being brought into relation with articles of food or drink. For example, the reprehensible practice of rinsing milk cans in water of this class may specially be cited. Again, watercress is frequently grown in sewage-polluted water.

It has been asserted that there is danger in eating fish caught in sewage-polluted streams. But any danger that might be supposed to exist should be removed by cleaning and cooking the fish. In the case of oysters and other shell-fish (tidal waters), when eaten in the raw condition the risk, however, may be a very real one.

There would also seem to be some danger of wells in the vicinity of polluted streams becoming contaminated. Soil is a very perfect filter under ordinary conditions, but sometimes fissures exist which may allow sewage matters to travel for a considerable distance in a practically unaltered condition. Moreover, soil may in course of time become so polluted as to be saturated with germs, and in such cases the microbes tend more and more to spread beyond their original limits. Lastly, floods may carry sewage-polluted water over the surface of adjoining land and so contaminate wells.

Some authorities consider that cattle suffer from drinking the water of sewage-polluted streams. But of this there is no very definite proof.*

Then there is the question of flood water depositing suspended matter and innumerable bacteria on the river banks. These in the dry condition may be carried by the wind for a considerable distance.

The possibility of danger to health from the inhalation of noxious gases is a separate question, and will not be considered here.

These factors, considered separately, may be of no great importance; taken together they cannot, as it seems to me, be entirely ignored.

A broad view of the case would seem to be that the danger is not abundant or far-reaching; that it tends to affect individuals rather than large communities. And although a single case of typhoid fever may, if circumstances favour it, create a widespread epidemic, too much stress should not be laid on concrete instances, but reliance placed rather on general considerations.

After careful consideration, I should be inclined to say that in the case of non-drinking streams—*except where oysters and other shell-fish which are eaten raw are concerned*—the bacteriological character of an effluent is of secondary importance.† But even from this secondary point of view the bacteriological examination may be of considerable utility for ascertaining the actual or potential putrescibility of an effluent.

Critics will be ready to note one circumstance; namely, that bacteriologists seem unable to say exactly the kind of microbes which, by their presence or relative abundance in an effluent, prove the presence of unfermented organic pabulum, and which therefore are to be thought of as peculiarly associated with the production of offensive putrefactive processes. All microbes are, however, in a sense putrefactive, and even pure water contains microbes which, in the presence of unconverted organic matter, can give rise to a putrescent effect. Recently some little progress has been made in this direction. Sewage, our standard liquid in the foul sense, contains gas-forming bacteria of the objectionable Coli and Proteus class in great abundance. Potable water, our standard in the pure sense, does not contain these microbes or contains them in small proportion only. Between these two extremes, and at any point between them, the number of gas-forming bacteria would seem to be a not unsatisfactory index of the amount of putrescible matter still remaining in the liquid. In other words, side by side with the destruction of the substance or substances which render sewage an offensive liquid there is a corresponding decline in the number of these gas-forming bacteria. If this were absolutely true, the estimation of the number of gas-forming bacteria would be of singular importance. Unfortunately, it is only approximately true, and the reasons are fairly obvious. As already said, in bacteria beds the process is so rapid that we may get a speedy destruction of the putrescible matter without a corresponding decline in the number of putrefactive bacteria, while the size of the fragments of coke or other substance composing the bed is commonly such as to preclude the possibility of the mere mechanical separation of the germs in question. In land treatment, on the other hand, the process is in comparison slow, and the destruction of the organic matter and the decline in the number of these bacteria to a corresponding extent

* † It may, however, be mentioned that in my examination of the process of septic tank followed by contact beds at Yeovil, I have found anthrax in large numbers, not only in the tank itself, but also in the coarse and fine beds. This examination was made some five months after the works had ceased to be used, and I could not therefore examine the final effluent, although the inference would seem to be that anthrax spores must have been present occasionally, if not habitually, in the final effluent. The question of the extent of danger to cattle in consequence of the presence of anthrax in streams from which they drink is not one easily answered. But it seems to me obviously desirable to exclude anthrax from such streams if this be practicable

may go hand in hand. But sometimes we seem to get a mechanical separation without a corresponding destruction of the putrescible organic matter in solution. Thus, of two effluents, the one from a bacteria bed process, the other from land—both containing a very similar amount of organic matter—the former might contain numerous gas-forming bacteria, and the latter relatively few. In this connection it is worthy of note that the rapidity of the bacteria bed processes, although of great practical value, is from the epidemiological point of view a positive disadvantage. For if there be any truth in the assertion that pathogenic germs are apt to be destroyed in a nutrient liquid like sewage, owing to the competing influence of their more hardy saprophytic neighbours, "delay" would seem to be an all-important factor.

The position of the bacteriologist would really seem to be this:—

Putrefaction cannot take place (whatever the number and sorts of bacteria present may be) in the absence of putrescible and oxidisable organic matter, and we have no direct means of estimating dead organic matter.

Indirectly, however, we can in most cases obtain a reliable indication of the degree of putrescibility of a liquid by estimating the number and observing the character of the bacteria contained in it.

In brief, our position as regards non-potable streams is very much that of the chemist in relation to drinking streams. In both cases the truth is sought for by necessarily indirect methods, and by assuming a relationship in the former case between the number of putrefactive bacteria and the amount of organic matter and in the latter case between the amount of organic matter and probable presence of microbes of pathogenic sort.

Up to the present the so-called incubator test has been largely practised by the chemist. But as it is based on the effect produced on the organic matter present in a liquid by the action of the bacteria in that liquid, it would seem to be a biological test.

In the present state of our knowledge it would seem unwise to reject altogether a bacteriological standard. It is impossible to forecast the future, and if a bacteriological standard can be brought into harmony with a chemical one it may be the means of strengthening our position and covering deficiencies in the chemical standard at present unforeseen and unsuspected. It must be remembered that the chemist in estimating the amount of organic matter is dealing with a substance about which he knows very little.

Moreover, the chemist can hardly, if at all, say of any effluent that it is insusceptible to putrefaction. All he can say is that under laboratory and artificial conditions of experiment it does not putrefy, and that his experience teaches him that a liquid having its particular chemical composition does not commonly give rise to an obvious or appreciable putrescent effect when discharged into an ordinary stream. It is always well to remember that a liquid giving rise to little or no appreciable smell when stored in a small bottle may yet conceivably when discharged into a river in huge bulk give rise to a very real and apparent nuisance.

Before leaving the subject note may be taken of the fact that some authorities assert that when an effluent is discharged into a non-drinking stream, it is both necessary and advisable that the bacteria which have been associated with its more or less complete purification should go with it also to continue their good work in the river. That it is necessary may be doubted, because river water already contains the microbes of putrefaction and nitrification. That it is advisable may conceivably be true, but there is no proof to show that such is the case.

In final summary it is to be noted:—

1. That both bacteria bed processes and land processes can yield effluents seemingly non-putrescible.

2. That in general the effluents from bacteria beds and from land are not to be thought of as safe in the case of drinking streams.

3. That chemical standards are essential in the case of potable and non-potable rivers.

4. That a bacteriological standard is most certainly indicated in the case of drinking streams, and is of more importance than the chemical one.

5. That a bacteriological standard is of secondary importance in the case of non-drinking streams, but may prove useful as an adjunct to the chemical standard.

A. C. HOUSTON.

February 26th, 1901.

Report on the Presence of Anthrax at Yeovil in (1) Septic Tank Liquor; (2) Septic Tank Sludge; (3) Primary Coarse Coke Bed; (4) Secondary Fine Coke Bed; (5) General Effluent from Final Catch-pit in a Hide Factory; (6) Mud of River Yeo; and (7) Mud of Yeo Brook.

By Dr. *Houston.*

On March 22nd 1901, Dr. McGowan visited Yeovil, and collected and transmitted to me samples of septic tank liquor and septic tank sludge. The results of the bacteriological examination of these samples led to my visiting Yeovil on April 12th with Dr. McGowan and Dr. Gordon. On April 24th and May 3rd Mr. Kershaw paid a third and fourth visit to Yeovil on behalf of the Commission, and besides collecting a number of samples, made certain inquiries of a useful kind, which I have incorporated in this Report (Addendum A).

Before entering into a description of the results of the experiments it is necessary to explain that the particular septic tank and coke beds have been out of use since last November, the reason being that the experiments which had been conducted during a period of about four years were considered by those in authority at Yeovil to be entirely satisfactory, and to justify the expenditure of a large sum of money on similar works, but large enough to treat the whole volume of Yeovil sewage, instead of only a section of it.* In the past, the whole bulk of Yeovil sewage has been discharged (and is now being discharged) *without any treatment*† either directly into the Yeo (the major portion) or indirectly into a brook (the minor portion) which joins the river Yeo above the main outfall.‡ The Yeovil sewage has the reputation of being excessively foul, and the foul character of the sewage is attributed to the large proportion of trade refuse present in it. The worst part of the trade refuse is derived from twelve or more hide factories, although two or more breweries play a minor part in rendering the sewage offensive. As regards the section of sewage treated in the experimental septic tank and coke beds, this was believed to contain more trade refuse relative to domestic sewage and surface water than will be the case when the total volume of sewage (all the domestic sewage, surface water, and trade refuse) is subjected to treatment at the proposed new works.

The following is a summary of the several sections of this Report:—

Part I. Relating to experiments with septic tank liquor and sludge collected on March 22, 1901.

Part II. Relating to experiments with samples collected from various sources on April 12, 1901.

Part III. Relating to experiments with other samples collected on the same date (April 12, 1901).

Part IV. Relating to experiments with samples collected by Mr. Kershaw on April 24, 1901.

---

* It should be added that provision has been made for final treatment on land.

† Some years ago an attempt was made to treat the sewage with flour of lime.

‡ A consideration of this fact leads me to remark that however useful it may be to keep before one a counsel of perfection, it is imperative to avoid relegating to the background a common-sense view of the whole subject of sewage disposal.

PART I.—RELATING TO SAMPLES OF STAGNANT SEPTIC TANK LIQUOR AND SEPTIC TANK SLUDGE, COLLECTED BY DR. McGOWAN ON MARCH 22ND, 1901.*

Sample 1.—SEPTIC TANK LIQUOR.—The sample represented a mixture of liquid taken from different depths. (Namely, one, three, and five feet towards the upper end; and one, three, and four feet towards the lower end of tank.)

Experiment 1.—The bottle containing the liquid was shaken, and 4 cc. were injected subcutaneously into a guinea-pig. The animal died on the sixth day, and cultivations made from the heart's blood yielded a pure culture of the anthrax bacillus (B. Anthracis).

Experiment 2.—Same as Experiment 1, but only 2 cc. were used for inoculation purposes. The guinea-pig died on the seventh day. An examination of the heart's blood, splenic juice, etc., showed the presence of anthrax bacilli in great abundance. Cultivations were made from the heart's blood, and they yielded B. Anthracis in pure culture.†

Sample 2.—SEPTIC TANK SLUDGE.

Experiments 1 *and* 2.—The bottle containing the semi-liquid, black coloured sludge was shaken. When the grosser particles had subsided, a portion of the supernatant liquid was poured off, and 2 cc. (experiment 1) and 1 cc. (experiment 2) of this liquid were used for the subcutaneous inoculation of two guinea-pigs. The animals died respectively on the third and fourth day, and their blood and tissues were found to be teeming with B. Anthracis. Moreover, cultivations made from the heart's blood in each case yielded anthrax in pure culture.‡

These experiments form an important link in the chain of evidence which goes far to prove that, however great the advantages of the septic tank treatment of crude sewage may be from the chemical and practical point of view, the assumption that the process destroys all the pathogenic microbes of sewage is ill-founded and untrustworthy. It is true that the above experiments do not absolutely prove that the effluent from the septic tank contained B. Anthracis, but having regard to their positive character when dealing with comparatively small amounts of the tank contents, the presumption in favour of such a view is of the strongest kind.§ They, of course, conclusively proved that anthrax must have been present at one time in the section of Yeovil sewage treated in the septic tank.

PART II.—RELATING TO SOME OF THE SAMPLES COLLECTED DURING MY VISIT TO YEOVIL ON APRIL 12TH, 1901.

Sample (6).—*Coke in Coarse Bed* (*Number* 2).‖—The coke was dug up to a depth of about $1\frac{1}{2}$ feet, and the fragments mixed together so as to yield an average sample. Some of this mixed coke was placed in a wide-mouthed, stoppered bottle.

Experiment 1.—360 grammes of coke were placed in a wide-mouthed, stoppered bottle, and 36 cc. of sterile water added. The bottle was shaken vigorously for some time, and then left undisturbed for two days. Then another 72 cc. of sterile water were added, the bottle well shaken, and a portion of the liquid (coke "washings") poured off into a small beaker. After allowing the grosser particles to subside, about 10 cc. of the comparatively clear liquid were

---

* Septic tank in operation about four years. At rest since last November, the liquid being left in the tank.

† The septic tank liquor strain of B. Anthracis will be hereafter referred to as strain I., *see* Figs. 1, 2, 3.

‡ The septic tank sludge strain of B. Anthracis will be hereafter referred to as strain II. (Figs. 4 and 5).

§ Proof, however, is furnished by the results of the coke-bed experiments.

‖ Said to have been treated with the septic tank effluent for four years. At rest since November, 1900.

decanted into a test tube. The tube was heated to 80 deg. C. for ten minutes so as to kill all the bacilli not present in the form of spores. 1 cc. of the surface liquid was withdrawn from the test tube by means of a sterilised glass pipette, and this was injected subcutaneously into a guinea-pig. The animal died on the second day, but I was unable to demonstrate the presence of anthrax either by examination of the blood and tissue juices, or by cultures therefrom.

Experiment 2.—In this experiment 10 cc. of the coke "washings" were poured off and diluted to 50 cc. with sterile water. After the grosser particles had subsided, 10 cc. of the liquid were decanted into a test tube, and the tube was heated to 80 deg. C. for 10 minutes. 1 cc. of the surface liquid was withdrawn from the tube and injected subcutaneously into a guinea-pig. The animal, however, eventually recovered completely from the effects of the injection.

Experiment 3.—5 cc. of the coke "washings" were poured off, diluted with sterile water to 10 cc., and heated in a test tube to 80 deg. C. for 10 minutes. 1 cc. of the surface liquid was used to inoculate (subcutaneously) a guinea-pig.

The animal died on the fourth day, and anthrax bacilli were present in large numbers in the blood and organs. Cultivations from the heart's blood yielded B. Anthracis in pure culture.*

The results of the last experiment proved conclusively that the septic tank effluent must occasionally, if not habitually have contained anthrax. It did not prove that the anthrax bacillus escaped in the effluent from the coarse bed.† But as we know that contact beds allow of the passage through them of bacteria of all sorts and of their spores in great abundance, it may be inferred that in all probability the effluent from the coarse coke beds occasionally or habitually contained the spores of B. Anthracis.

Sample (7).—Coke in Fine Bed (Number 8).‡—A mixed sample of the coke was obtained in the same way as in the case of sample (6).

Experiment 1.—620 grammes of the fine coke were placed in a wide-mouthed, stoppered bottle, and 62 cc. of sterile water added. The bottle was shaken repeatedly and then left undisturbed for two days. Next another 124 cc. of sterile water were added, and, after shaking vigorously, a portion of the liquid (coke "washings") was decanted into a small beaker. The grosser particles were allowed to subside, and afterwards 10 cc. of the comparatively clear surface liquid were poured into a test tube and heated to 80 deg. C. for 10 minutes. By means of a sterilised pipette 1 cc. of the surface liquid was withdrawn from the test tube, and this was injected subcutaneously into a guinea-pig.

The animal died on the second day, and its blood and organs were found to contain B. Anthracis in abundance. Cultivation made from the heart's blood yielded Anthrax (B. Anthracis) in pure culture.§

The result of this experiment affords adequate proof that the spores of B. Anthracis were not only stored in the coarse coke bed but came away in the effluent from that bed.

Summary at this Stage.

In summary at this stage it is to be noted that :—

(1) The liquor and sludge in the stagnant septic tank contained anthrax. Therefore the anthrax bacillus must at one time have been present in the section of Yeovil crude sewage treated in the septic tank.

(2) The coarse coke bed "washings" likewise contained anthrax, and therefore this pathogenic microbe must have been sometimes present in the septic tank effluent.

(3) The spores of the anthrax bacillus were also present in the fine coke bed "washings," and therefore they must have been present in the effluent from the coarse coke bed.

As the works were no longer in use, there was no way of proving by direct observation that the final effluent from the fine beds ever contained

---

* The coarse coke bed strain of B. Anthracis will be hereafter referred to as strain III. (Figs. 6 and 7.)

† Proof, however, is furnished by the results of the fine coke-bed experiments.

‡ Said to have been "treated" with the effluent from the coarse coke bed for over twelve months.

§ The fine coke bed strain of B. Anthracis will be hereafter referred to as strain IV. (Figs. 8, 9, 10).

TABLE 1.—SHOWING CERTAIN FACTS AND INFERENCES TO BE DEDUCED FROM THE YEOVIL ANTHRAX EXPERIMENTS.

The Presence of Anthrax in—

The stagnant septic tank liquor and in the sludge	afforded proof of the presence at one time of anthrax in Yeovil crude sewage and	led to the inference that the septic tank effluent contained anthrax.				
The coarse coke bed			afforded proof of the presence at one time of anthrax in the septic tank effluent and	led to the inference that the coarse coke bed effluent contained anthrax.		
The fine coke bed					afforded proof of the presence at one time of anthrax in the coarse coke bed effluent, and	led to the inference that the fine coke bed effluent contained anthrax.

anthrax. But the presumptive evidence in favour of this is of so strong a kind that to hold an opposite view would be to take up, in my opinion, a quite untenable position.

The above facts and inferences are set forth in Table I. It will be seen that the only flaw in the line of argument is the absence of proof that the effluent from the secondary fine coke-bed contained, on occasion, anthrax From our knowledge of the biological qualities of the effluents from secondary fine coke bacterial beds, we may reasonably consider the chain of proof complete.

It is of some moment to avoid taking an extreme view, whether trivial or exaggerated, of the importance of these observations. To adopt a complaisant attitude would be to ignore the fact that *B. Anthracis* can give rise to a most dangerous disease in human beings, although happily only rarely and seldom so far as we know in epidemic form,* and also to place on one side the causal relation of anthrax to splenic fever, a most deadly scourge among cattle. But to take up an alarmist position in this matter would be equally harmful and inconsistent with the fact that, notwithstanding the discharge for many years of the *untreated* crude sewage of Yeovil into the River Yeo, no special and peculiar incidence of anthrax has, to the best of my knowledge, been traced to that particular source.†

I would rather from these experiments point out a general lesson, namely, that however satisfactory bacterial processes of purification may be from the chemical and practical points of view, they are not to be thought of as eliminating all risk of danger to health either as regards human beings or the lower animals.

Possibly the results of these experiments afford reasonable grounds for compelling particular manufacturers to undertake the sterilisation of trade refuse of a dangerous sort.

But the practical difficulties involved in the destruction of anthrax spores are, unfortunately, very great. Moreover, chemical or physical agents destructive of anthrax spores would also destroy most, if not all, the bacteria concerned in the bacterial purification of sewage.‡ Further, chemical substances markedly poisonous to animals and fish could hardly be employed with safety in all cases. If the amount of sterilised trade refuse gaining entrance into the sewers was small in relation to the total bulk of sewage this would, perhaps, not matter very much, as the sterilising substance would, applied in the manufacturer's premises, be so diluted at the outfall works as to weaken or destroy its antiseptic or injurious quality.

Again, if the chemical substance employed was one which, though used at the outfall, could be neutralised or got rid of in one way or another so far as its injurious qualities were concerned, the above objections would be removed. Unfortunately, it may be doubted if there are any germicidal agents known which are innocuous to man, the lower animals, and fish life, when used in the strength necessary to destroy anthrax spores.

---

* Human *intestinal* anthrax is, fortunately, a very rare disease. But it is possible that unrecognised cases may sometimes occur. Butler and Karl Huber (quoted by Osler in his text book of medicine) described an epidemic in which twenty-five persons were attacked with intestinal anthrax after eating the flesh of an animal which had had anthrax. Six cases ended fatally. Infection of the human subject in nearly all cases is through the accidental inoculation of a surface abrasion, wound or pimple (malignant pustule), or else by the inhalation of the spores (pulmonary anthrax or wool-sorter's disease).

† Since writing the above, further enquiries have been made, and the results are not altogether reassuring. Although no cases occurring in human beings have been reported within recent years, the same cannot be said as regards the lower animals. Quite a number of cases of *alleged* anthrax have been reported from farms in the neighbourhood. The source of the infection is locally ascribed to (1) contamination of the river Yeo with trade refuse, and (2) the *extensive use* of the "refuse" from the hide factories as *field manure*. I consider it probable that the latter has been the main source of infection. In 1892, Somerset stood third among all the counties of England as regards the number of outbreaks of anthrax.

‡ Anthrax spores are said to be destroyed in a formalin solution of 1 : 1,000 in one hour. But my own experiments do not confirm this. Mercuric chloride is efficient in the proportion of 1 : 1,000, some say within a few minutes, others within half an hour, others again consider one hour's contact necessary. A 1 to 5 per cent. solution of calcium hypochlorite is necessary for the destruction of anthrax spores. Duration of contact variously stated ; some authorities consider a few minutes sufficient, others extend the time up to one hour.

Part III.—Relating to further Samples collected during my Visit to Yeovil on April 12th.

Series I.

Sample (1).—General Sewage (all domestic sewage, surface water, and nearly all trade refuse) near outfall into Yeo.

Experiment 1.—1,000 cc. of the liquid were placed in a Blyth's sedimentation apparatus. On the second day the deposit (about 3·5 cc.) was diluted to 10 cc., and then heated to 80 deg. C. for ten minutes in a test tube. 1 cc. of the surface liquid was withdrawn by means of a sterilised glass pipette, and injected subcutaneously into a guinea-pig. The animal died on the second day, but not from anthrax. Cultivations from the heart's blood yielded negative results.

Experiment 2.—A further experiment was made, but with a lesser quantity of the sedimented liquid. The animal, however, recovered completely.

Sample (2).—Brook Water.—This brook joins the River Yeo just above the main sewer outfall. It is seemingly not contaminated with domestic sewage, but two or more hide factories discharge their refuse into it.

Experiment 1.—The experiment was carried out in the same way as Experiment 1 Sample (1), except that the deposit (about 3·5 cc.) was not diluted. Further, after heating to 80 deg. C. for ten minutes in a test tube, the contents of the tube were shaken, and 1 cc. of the shaken liquid was used for inoculation purposes. The guinea-pig completely recovered from the effects of the injection.*

Series II.

Sample (3).—Semi-Solid Filth and Slime, held back by batten in manhole of sewer which previously supplied septic tank.

Sample (4).—Crude Sewage from the same place.

Sample (5).—Liquid from First Tank (Soak-pit) in Hide Factory (A.).—Situated lower down the brook than the septic tank. Represents the dirty liquid resulting from the first "washings" of a batch of hides.

Sample (8).—Surface Liquid in Septic Tank.

In each case a portion of the liquid† was heated to 80 deg. C. for ten minutes, and guinea-pigs were severally inoculated subcutaneously with 1 cc. The result was negative except as regards Sample (3), and here death was not due to anthrax.

Further experiments were made with Samples (4) and (5), but the liquid, instead of being shaken, was left at rest for seven days, and then part of it was poured off, and 1 cc. of the remaining liquid, which contained most of the suspended matter, was used for inoculation purposes. The result was negative as regards Sample (4), and although the guinea-pig inoculated with Sample (5) died on the third day, death was not due to anthrax.

Another experiment was also made with Sample (8), and here the liquid was not heated to 80 deg. C. for ten minutes, as in all the foregoing experiments. Further, the 1 cc. used for inoculation purposes contained more suspended matter than in the previous experiment with the same sample. The guinea-pig died on the third day, and, on examination, the heart's blood and spleen juice contained some bacilli which could not with certainty be said not to be anthrax. But cultures made from the heart's blood gave no growth, and death was doubtless due to some micro-organism other than B. Anthracis, probably a pathogenic anaerobe.

In summary of Part III. it is to be noted that all the samples yielded negative results as regards anthrax.

It was, perhaps, hardly to be anticipated that chance samples of the crude sewage and brook water should yield a positive result under the conditions of experiment. But the negative result in the case of Sample (5) is of considerable interest, since it seems to indicate that the foul liquid resulting from the primary process of steeping and washing a large number of hides need not of necessity contain anthrax.‡ Indeed, it gives rise to the supposition that the presence of anthrax is dependent on the introduction into the primary tank of a special batch of specifically contaminated hides. If this be true, then the danger in the case of a single factory may be only an occasional and accidental one.§ Nevertheless, the septic tank results lead

---

* The difficulty in all these experiments was this :—If a large dose was employed, the animal was liable to rapidly die from the pathogenic effects of microbes other than anthrax. If a small dose was used, the chances of anthrax being present were correspondingly reduced.

† In the case of Sample (3) the liquid drainings from the semi-solid filth was used.

‡ It is here assumed, possibly without sufficient justification, that the primary tank would be specially liable to contain anthrax.

§ Too much stress, however, must not be laid on the results of the examination of a single sample.

one to suppose that, if anthrax was not commonly present in the trade refuse, its numbers on the occasions when it was present must have been very great. It must, however, also be taken into consideration that the septic tank and coke beds had been in operation for a very long period. In my previous writings (*e.g.*, *British Medical Journal*, Aug. 18th, 1900) I have hinted at the possibility of bacterial filters acting as a storehouse for pathogenic germs; and the same may be true as regards septic tanks and certain microbes. In this sense possibly the septic tank acted as a storehouse for anthrax spores, and, while allowing of the escape in the effluent of a certain number of them, yet held back the majority in the sludge at the foot of the tank. Even so, however, a time would doubtless arrive when the inflow to the tank and the effluent therefrom would contain an approximately equal number of spores. One alternative remains—namely, the possibility of anthrax multiplying in the septic tank. All that can be said in this connection is that our present conceptions of anthrax, when existing under saprophytic conditions, are in favour of its remaining alive only when lying dormant in the form of spores.* Moreover, the anaerobic conditions prevailing in the septic tank would seem to place the possibility of multiplication of this aerobe almost out of the question. The spores might, indeed, germinate into bacilli and the bacilli again form spores in the bacteria beds, but this appears to me to be very unlikely.† Nor is it probable that the above developmental changes could take place either in the tanks (in the hide factories) or subsequently in the sewers. There is reason to think that from first (*i.e.*, starting with the hides specifically contaminated with anthrax spores) to last (*i.e.*, ending with the presence of anthrax spores in the fine coke bacterial bed) little or no developmental change occurred of the nature of germination of the initial spores into bacilli, multiplication of these bacilli, and, finally, of their sporulation.

Part IV.—Relating to Samples Collected by Mr. Kershaw on April 27th, 1901.

Series I.

Sample (256).—Liquid from First Tank (soak-pit) in hide factory (B), situated above septic tank. The refuse from this factory formerly went into septic tank, and now is discharged into the brook. The liquor had been four days in contact with hides, and represents the dirty liquid resulting from the first "washings" of a batch of hides. Capacity of tank 6 feet by 6 feet, by 4 feet deep.

Sample (257).—Lime Liquor from Tank in same factory. This lime liquor had been in its tank six weeks, and hides out of it about three weeks.

Sample (258).—General Effluent from final Catch-pit (bran, lime, and soak-pit refuse) in same factory.

Sample (259).—Crude Sewage from last manhole at the outfall.

Sample (263).—Yeo Brook, which joins the River Yeo just above the main sewer outfall. Sample taken from a point near experimental works and below all the hide works which used to discharge into the septic tank and which now discharge into the brook.

In each case 700 cc. of the liquid were poured into sterile bottles.

As regards Samples 258 and 259 the bottles were shaken and 1 cc. used (without preliminary heating to 80 deg. C.) to inoculate guinea-pigs (g.p. 258 and g.p. 259).

As regards the other samples, the bottles were placed on one side for twenty-four hours to allow sedimentation to take place. Then a small portion of the sediment was in each case sucked up with a sterilised pipette and 1 cc. used (without preliminary heating to 80 deg. C.) to inoculate guinea-pigs (g.p 256; g.p. 257; and g.p. 263).

In two days g.p. 256 and g.p. 259 were dead, but not seemingly from anthrax. Cultures made from their heart's blood were sterile as regards B. Anthracis.

Guinea-pigs 257 and 263 eventually recovered from the effects of the injection.

---

* It is perhaps hardly necessary to point out that anthrax within the animal body is always present in the bacillary form, never as spores. But the blood and discharges of affected animals contain the bacilli in great abundance, and on exposure to the air spores are readily formed. In this way hides become infected with the highly resistant spores of this pathogenic microbe. Splenic fever (anthrax in cattle) is not very common in this country, but abroad the disease occurs as a regular scourge. Unfortunately most of our hides are imported.

† As regards temperature, the limits of development are usually stated to lie between 12 deg. C. and 45 deg. C., and of spore formation between 18 deg. C. and 40 deg. C. But authorities differ on this point.

But guinea-pig 258 died on the fourth day, and on examination the blood and splenic juice were teeming with B. Anthracis. Cultures made from heart's blood yielded B. Anthracis almost in pure culture.*

Series II.

Sample (260).—Mud from the banks of the Yeo. 150 feet below sewer outfall.

Sample (261).—Ditto. About 1,150 feet below 260.

Sample (262).—Ditto. About 4,150 feet below 260.

185, 260, and 492 grammes respectively, of Samples 260, 261, and 262 were mixed (each in a separate wide-mouthed stoppered bottle) with 100 cc. of sterile water. After shaking for some time and then allowing the grosser particles to subside, a small quantity of the supernatant liquid was poured off, and 1 cc. (without preliminary heating to 80 deg. C.) was used to inoculate guinea-pigs (g.p. 260; g.p. 261; and g.p. 262).

Guinea-pig 261 recovered; g.p. 262 died on the eighth day, but not from anthrax.

But g.p. 260 died on the third day, and the heart's blood and spleen were found to be swarming with anthrax bacilli, and cultures from the heart's blood yielded B. Anthracis.†

The experiments were repeated as regards 261 and 262, somewhat large quantities being used. G.p. 261 recovered; g.p. 262 died, but not from anthrax.

In Summary of Part IV. it is to be noted that all the samples yielded negative results as regards anthrax with the exceptions of Sample 258 (general effluent from final catch-pit [bran, lime, and soak-pit refuse]), and Sample 260 (mud from the banks of the Yeo, 150 feet below sewer outfall).

The demonstration of anthrax in the mud of the River Yeo must not be taken as affording any proof that the final effluent from the fine coke-bed contained B. Anthracis. Although there can be little doubt that the fine-coke-bed effluent did contain the spores of anthrax (in view of their presence in abundance in the material composing the bed), it is highly probable that the presence of anthrax in the river mud was due to the continuous discharge into the River Yeo of untreated crude sewage and trade refuse.

Part V.—Relating to Samples Collected by Mr. Kershaw on May 3rd, 1901.

Sample (268).—Septic Tank Liquor taken 18 inches below the surface.

Sample (269).—Mud from banks of brook which joins Yeo lower down. Sample collected between last factory discharging into brook above septic tank and point opposite septic tank.

Sample (271).—From the same tank as Sample 256. Collected while the tank was being emptied.

Some of the liquid from the bottle containing Sample 268 was heated to 80 deg. C. for ten minutes. Then 10 cc. were centrifugalised, and 8 cc. poured off, and the remaining 2 cc. used to inoculate a guinea-pig. The animal eventually recovered from the effects of the injection. The experiment was repeated, but 50 cc. instead of 10 cc. were centrifugalised, and 48 cc. poured off, and 2 cc. used for inoculation, but the animal recovered.

From the results of the experiments with Sample (8), Series II., Part III., and Sample 268, Part V., it is evident that the spores of B. Anthracis cannot have been equally diffused throughout the whole contents of the septic tank.

405 grammes of Sample 269 were mixed with 100 cc. of sterile water in a wide-mouthed stoppered bottle. After shaking for some time the mixture was allowed to partially settle. Then 10 cc. of the comparatively clear liquid were syphoned off, heated to 80 deg. C. for ten minutes, and 1 cc. used to inoculate a guinea-pig. The animal eventually recovered from the effects of the injection. The experiment was repeated, but 2 cc. instead of 1 cc. were used for inoculation purposes. The animal died on the third day, and, on examination, the blood and spleen juice were teeming with B. Anthracis. Cultures from the heart's blood yielded B. Anthracis in pure culture.‡

As regards Sample 271, a portion of the liquid was heated to 80 deg. C. for ten minutes, and 1 cc. used to inoculate a guinea-pig, but the animal eventually recovered.

In summary of Part V. it is to be noted that only sample 269 yielded a positive result as regards anthrax. The mud was clearly contaminated from the two or three factories located higher up the brook than the septic tank.

---

* This strain of anthrax will be hereafter referred to as strain V.

† This strain of B. Anthracis will be hereafter referred to as strain VI. (Fig. 11.)

‡ This strain of anthrax will be hereafter referred to as strain VII. (Figs. 12 and 13.)

These hide factories must necessarily from their situation have been those concerned in polluting the septic tank with the spores of B. Anthracis, for during the period when the septic tank was in operation, the refuse from these factories, instead of being discharged into the brook, was diverted into that section of the sewerage system leading to the septic tank.

A.—GENERAL SUMMARY.

In general summary of all the positive results, it is to be noted that seven strains of anthrax were obtained from seven different sources, as follows :—

Strain I. Septic tank liquor.
,, II. ,, sludge.
,, III. Washings of coke from primary coarse coke bed.
,, IV. ,, ,, secondary fine ,,
,, V. General effluent from final catchpit in a hide factory.
,, VI. Mud from the banks of the River Yeo.
,, VII. ,, ,, ,, Yeo Brook.

It has already been explained that the presence of anthrax in the septic tank proves, in the first place, that the section of sewage and trade refuse treated at the experimental works must at least occasionally have contained anthrax: secondly, that the presence of anthrax in the primary coarse coke bed proves that the septic tank effluent must at one time or another have contained anthrax; and, lastly, that the presence of anthrax in the secondary fine coke bed proves that the effluent from the primary coarse coke bed must at one time or another have contained anthrax.

The demonstration of anthrax in the general effluent from a final catchpit in a hide factory merely shows that the particular factory concerned must have been dealing with anthrax infected hides at one time, and probably at a period not far remote from the time when the sample was collected.

The presence of anthrax in the mud of the banks of the River Yeo and Yeo Brook is of considerable interest, and shows the great importance of examining in similar circumstances the sides and bed of a stream, as well as the flowing water.

The spores of anthrax are peculiarly resistant. That they would in the case of the Yeo be swept from the banks in time of flood and carried when present in the mud or river bank, down the river to be spread over low-lying land bordering the river hardly admits of any doubt. This seems a most serious matter, and certainly the "widening of the potentially infective anthrax area" by means of flood water is a subject which demands careful scrutiny. But it does not follow that a "potentially infective" area need ever become an "actually infective" one. It seems highly probable that with all diseases of bacterial origin a certain dose of poison is required to start the infective process. This may be less true with anthrax than in the case of some other diseases, but it holds good to some extent. It is by no means inconceivable that flood water while "widening the potentially infective anthrax area" might affect so wide a separation of the individual spores of anthrax one from the other as to largely remove the element of danger. Thus in the case of a low-lying pasture flooded with river water containing anthrax spores, the total number of anthrax spores deposited on the land might, if collected together, suffice for the infection of a large herd of cattle. But widely separated from each other, they might not readily infect grazing cattle, and even spores, like other matters, may in time undergo dissolution. It is here assumed, be it noted, that unless under very peculiar and special conditions the spores of anthrax remain dormant (under natural conditions) in the form of spores, and do not germinate into bacilli and multiply to any great extent if at all. It needs to be added that these remarks must not be read as implying that the presence of anthrax in

the various situations I found it to be in at Yeovil is unimportant. The contrary is the case, but it serves no useful purpose to magnify the danger and risk distorting things out of their true proportion. Excluding any case that may have arisen in the past from direct infection from handling the hides, and excluding also infection of cattle through grazing on land manured with the "refuse" from the factories, as foreign to the present inquiry, I am not aware that any special incidence of anthrax has been definitely traced in Yeovil or its neighbourhood to the discharge of untreated crude sewage and trade refuse into the river Yeo.*

It might have been anticipated perhaps that some of the strains of anthrax would have shown slightly diminished virulence as the result for example of prolonged sojourn in the septic tank and coke-beds. But unfortunately all the strains isolated were found to be of high virulence. Thus all the seven strains were subcultured in agar for one night at 37 deg. C. Seven mice were severally inoculated at the root of their tails with a platinum needle the point of which had been brought in contact with the growth on agar of one or other of the seven strains of B. Anthracis. The results were as follows :—

Strain	I.	Corresponding	mouse died in about 24 hours.
,,	II.	,,	mouse died in about 30 hours.
,,	III.	,,	mouse died in less than 24 hours.
,,	IV.	,,	mouse died in about 24 hours.
,,	V.	,,	mouse died in less than 24 hours.
,,	VI.	,,	mouse died in less than 24 hours.
,,	VII.	,,	mouse died in about 24 hours.

In supplement to the summary which has been given of the positive results, a reference is now made to some of the negative results.

Thus, although anthrax was found in the mud of the Yeo Brook and Yeo River within 150 feet of the main sewer outfall, negative results were obtained with two samples of mud collected, respectively 1,150 ft. and 4,150 ft. below the source of the last named sample.

Further, the spores of B. Anthracis were seemingly not distributed equally throughout the contents of the septic tank since samples 8 and 268 yielded negative results.

Lastly, negative results were obtained with a number of the samples notably number 5; as also with numbers 256 and 271 derived from the first "washings" of hides in the primary soak-pits, respectively of factories A (5), and B (256 and 271).

B.—CONCLUSIONS.

The new scheme for the disposal of Yeovil sewage provides for the treatment of the whole of the domestic sewage, trade refuse, and surface water, by means of septic tanks, and artificial filters with final disposal on land.†

From the results furnished in this report there are no good grounds for anticipating that the new scheme will remove the danger arising from the presence in the final effluent of living and virulent anthrax spores. That anthrax spores will eventually pass through the septic tanks, and bacterial beds can hardly be doubted. The land might possibly effect their mechanical separation if it were of good quality, but this would appear not to be the case. It must also be remembered that the grit chambers will require periodic cleansing, and that a time will come when the septic tanks and filter-beds will call for similar treatment, and that their contents will have to be disposed of. The question thus arises what action the Commission should take in this matter. It must be remembered that Yeovil is only one of a number of places where this question must of necessity be considered in the future.

* *See*, however, footnote (†) on page 5. † The land is stated to be not very suitable.

Three points appear to me worthy of consideration.

(1). Anthrax is a disease affecting man and other animals.

(2). The degree or probability of danger to man and animals at Yeovil.

(3). The question of what is practicable by way of remedy.

As regards (1) and (2) :—Intestinal anthrax in human beings is almost an unknown disease, although possibly cases may occasionally occur the true nature of which is not recognised. Further, the River Yeo is a non-drinking water stream. Infections through wounds, abrasions, or sores in connection with the discharge of sewage effluents into rivers may, perhaps, reasonably be ignored; or, at all events, regarded as of most unlikely occurrence. But bathing should certainly be prohibited in the neighbourhood of sewage outfalls in cases where the conditions are comparable to those pertaining at Yeovil. The danger, however, to human beings at Yeovil is to be looked for within the walls of the hide factories rather than outside them.

As regards animals the case is different, and there can be no doubt that here a real danger exists. That cattle drinking water containing anthrax spores or grazing on anthrax polluted land may become infected with anthrax is indisputable. Nevertheless, it must be borne in mind that a potential danger, seemingly of serious kind, may yet possibly never become an actual and tangible one. The incidence of anthrax on cattle in the neighbourhood is, in my opinion, to be ascribed rather to the manuring of the fields with refuse from the factories than to contamination of the River Yeo with the "untreated" crude sewage and trade effluents. Such an opinion, however, is necessarily little better than surmise, and without further investigation must be received with reserve.

As regards (3), no hopeful view can be expressed. To sterilise the whole of the sewage is out of the question; to sterilise the trade refuse alone seems impracticable.* It might be possible, although even this is doubtful, to sterilise a section of the trade refuse, namely, that portion most likely to contain the spores of anthrax. No process of sterilisation could reasonably be enforced which entailed a great expenditure, or which would be likely to injure the quality of the hides, or defeat the objects of the bacterial treatment of the sewage by destroying all the microbes in the general sewage.

The proprietors of a particular disinfectant on the market advise that hides should not be imported in a "sun-dried" condition, but should be painted over instead abroad with their preservative which they claim kills anthrax spores and leaves the hides in a more workable condition than if they were sun-dried.† The cost of such treatment is not serious, and if these claims be well founded, pressure might perhaps reasonably be brought to bear on manufacturers to induce them to require disinfected hides instead of sun-dried ones. The disinfectant in a 4 per cent. solution is said to be fatal to the spores of anthrax when infected hides are left soaking in it for one hour. This treatment is held to be non-injurious to the hides, and not very costly, and as it may be carried out by the consignee in this country may be suggested as an alternative to importing disinfected hides. The composition of the disinfectant is not stated, but it is admitted to be poisonous, which presents obvious disadvantages. It is proposed to test the germicidal value of a solution of this substance as regards anthrax spores, but there seems no easy way of ascertaining whether imported hides which have been "pasted" with the material abroad arrive in this country in a sterile condition as regards anthrax.‡

A considerable number of experiments have already been carried out with certain sterilising agents of comparatively speaking innocuous sort, but they are reserved for a special report on the sterilisation of effluents.

* The total volume of domestic sewage, manufacturing effluents (breweries and hide factories), and surface water amounts to about 143 million gallons per annum. The hide factory refuse amounts to about one-ninth part of the whole volume of sewage.

† After painting the hides with the preservative, natural or artificial, drying may be used, but "hard-drying" or "sun-drying" is not recommended.

‡ Since writing this Report the disinfectant has been tested with disappointing results.

I would urge somewhat strongly that the Commission should authorise me to inquire more fully into the matter, and to keep one or more factories under sustained observation so as to obtain some idea of the extent of the danger from anthrax and the best remedy.

Without making further inquiries and experiments, I am not prepared to express any decided opinion or come to other than tentative conclusions. The subject is indeed one which merits the most careful consideration on the part of the Commission.

In carrying out this piece of work I have received much valuable assistance from Dr. Gordon.

[Magnifying power, 1,000.]

Addendum A.

*Note on the Process of Hide Dressing as practised at Yeovil.**

The raw hides (sheep and lambs) are all said to be imported from the Cape, Russia, and Spain, and they arrive in this country in a "sun-dried" state.

1. *Soak-Pit Process.*—A batch (about 600) of hides are placed in a tank or soak-pit (about 8 feet by 8 feet by 4 feet deep), and covered with heavy planks to prevent them from rising. The tank is filled with pure water (town supply); and, after twenty-four to forty-eight hours, or longer, the hides are fished out and transferred to a second and similar tank for a like period. Fresh water is used for each fresh batch of hides, and the dirty water escapes into a catchpit, if there is one, if not directly into the sewer or brook.

* The information contained in this brief note was obtained for me by Mr. Kershaw.

This soaking process cleans and softens the hides. While the hides are in the tank they are occasionally stirred about with a stout pole. The liquid from the soak-pits represents about one-fourth to one-fifth of the total volume of water used in dressing the hides. Antecedent to the next process, the hides are taken out of the soak-pit and scraped on a beam with a blunt draw-knife, and piled in heaps (flesh side uppermost) on the stone slabs adjoining the soak-pits.

2. *Arsenic and Lime Pasting Process.*—The hides are next pasted (on the flesh side) with a mixture of red arsenic (orpiment, obtained from Saxony) and lime. About 5 lb. of arsenic and a bushel of lime are mixed to a thin paste with water in a tub, and the mixture applied to the hides with a piece of sacking tied to the end of a pole. Each hide, after pasting, is folded once, and the hides are left piled in heaps for about twelve hours, when the depilatory action is sufficiently advanced to allow of removal of the hair by scraping the hair side of the hides on the beam. The wool or hair is rinsed, dried on a drying floor, and sold to make blankets, etc. The hides are then rinsed in tubs (rinsings go to sewers) and are ready for the next process.

3. *Lime Process.*—The hides pass through a series of tanks (four, about 7 ft. by 4 ft. by 4 ft.) containing lime in varying amount (about 4 bushels to each tank), and the process occupies about three weeks. After two batches of hides have been "treated" the liquid is allowed to run to waste to the catchpit or sewer or brook, and the tanks cleaned out and made ready with fresh lime for a fresh lot of hides. After the lime tanks the hides are again placed on the beam and scraped, but preparatory to this they are thoroughly rinsed in tubs containing clean water.

4. "*Puring*" *Process.*—The hides are next "treated" in a "puring" bath of dog dung and water contained in tubs, the liquid being kept at a certain temperature. The period varies (average about four hours) according to the quality of the hides. The foul liquid resulting from this process passes to the catchpit or sewer or brook. A fresh solution is used for every batch of hides. The "puring" bath brings the hides into a pliable and workable condition. It is doubtless a biological process, and the first and third processes probably involve bacterial action as well. After rinsing, the hides are ready for the next process.

5. *Bran Drench Process.*—The hides are soaked in tubs containing bran and water for some hours and again put on the beam and further cleansed and rinsed.

6. *Alum* (*etc.*) *Process.*—The hides are placed in revolving drums and a mixture of alum, salt, flour, and yoke of eggs forced into them. They are then stove-dried, and the "staker" next softens them in water and then stretches them on stakes. They are then ready to be dyed and afterwards made into gloves.

The effluents and "rinsings" from all the different processes are run off whenever convenient, either directly to the sewers or brook, or indirectly through a catchpit.

The total amount of water used in all the hide factories amounts to over sixteen million gallons per annum. Of this about one-fourth to one-fifth approximately comes from the soak pits and about one-fourth from the line tanks.

The total volume of domestic sewage, manufacturing effluents (breweries and hide factories), and surface water amounts to about 143 million gallons per annum. The hide factory refuse thus amounts to about one-ninth part of the whole volume of sewage.

Report on the Results of the Subcutaneous Inoculation of Animals with Crude Sewage and with Effluents; Together with an Account of Detection of B. Pseudo-Tuberculosis and B. Pyocyaneus in some Samples of Sewage and of Effluents.

By Dr. *Houston.*

12*th February*, 1902.

This report can lay no claim to being a comprehensive study of the pathogenic qualities of sewage and effluents. The subject is a wide one, and to investigate it thoroughly would be the work of many years. But the esults obtained up to the present seem of sufficient importance to make it dvisable to place them on record.

The following is a list of the several sections of this report :—

I. Summary of previous work.
II. The subcutaneous inoculation of guinea-pigs with crude sewage and with effluents.
III. The subcutaneous inoculation of guinea-pigs with crude sewage previously heated to 80° C. for ten minutes.
IV. The subcutaneous inoculation of guinea-pigs with crude sewage previously heated to 100° C.
V. The subcutaneous inoculation of guinea-pigs with crude sewage after preliminary treatment as follows :—
  (*a*) Heated to 65° C. for twenty minutes and rendered germ-free by filtration through a sterilised Pasteur filter.
  (*b*) Heated to 80° C. for ten minutes and rendered germ-free by filtration through a sterilised Pasteur filter.
  (*c*) Heated to 100° C. for one hour and rendered germ-free by filtration through a sterilised Pasteur filter.
VI. The subcutaneous inoculation of guinea-pigs with crude sewage previously filtered through a sterilised Pasteur filter.
VII. The microbes concerned in producing the pathogenic results.
VIII. Pseudo-tuberculosis. B. pseudo-tuberculosis in sewage and sewage effluents.
IX. B. pyocyaneus in sewage and effluents.
X. Summary.
XI. Conclusions.

I.—*Summary of Previous Work.*

During 1898-99 I carried out a preliminary research on the subject of the bacteriology of sewage on behalf of the London County Council.

The following is a brief summary of the chief results then obtained :—

Injection of Crude Sewage and Effluents into Guinea-pigs.

A. The subcutaneous injection of Barking and Crossness crude sewage into guinea-pigs (about 1 to 3 cc. per 200 grms. weight), nearly always produced a local reaction, and not uncommonly death in from twenty-four to seventy-two hours. Sometimes the effluents from the coke beds were found to be more pathogenic than the raw sewage, but usually a somewhat larger dose of effluent than of sewage was required to produce a fatal effect.

B. If the injection of the crude sewage or effluent is not followed by fatal results within the first few days, the animal may occasionally die after the lapse of some weeks' time from pseudo-tuberculosis (*B. pseudo-tuberculosis* of A. Pfeiffer).

C. When the animal dies rapidly (twenty-four to seventy-two hours), virulent microbes, belonging to the class of B. coli and B. proteus may readily be isolated from the blood or tissues of the animal.

D. If the crude sewage or effluent be previously heated to 100° C. for one hour, large doses may be injected without producing a fatal result.

E. If the crude sewage or effluent be previously heated to 80° C. for ten minutes, a pathogenic effect may still be produced, but a much larger dose is usually required than when the liquid has not been so heated.

F. If the crude sewage or effluent be filtered through a sterilised Pasteur's filter, very large doses of the filtrate fail to produce a pathogenic effect.

The results that have since been obtained amply confirm the above statements. In addition some new information has been gained, notably as regards the presence of anthrax at Yeovil.*

Before considering the additional and confirmatory data it may be observed that the facts to be set forth not only show the actually dangerous qualities of some sewage effluents as regards rodents, but indicate also, and incidentally, for the same effluents possible danger to human beings. I say incidentally, because it does not, of course, follow that because an effluent produces a pathogenic effect when injected into rodents it would necessarily produce a pathogenic result if drunk by human beings. Nevertheless, we already know the dangerous qualities of sewage† in relation to human disease, and if the effluents from land and bacteria-bed processes of sewage treatment are apt to produce a pathogenic result equally with raw sewage when subcutaneously inoculated into rodents, the tentative inference is that it would be unwise to regard such effluents as being so altered by their treatment as to have ceased to be potentially dangerous in the case of human beings, however greatly the amount of their bacterial flora may be reduced.

As an index, then, of the retention by an effluent of the noxious qualities of its parent sewage and of the presence in it of undesirable microbes, the inoculation of animals is to be recommended, if not as a routine measure at least as an occasional test.

In this view of the case the pathogenicity of effluents in the case of rodents is significant, not because it, *pari passu*, directly points to danger in relation to human disease, but because it indirectly tends to show that a liquid (raw sewage), *not unknown* in its relation to human epidemic disease, has not, so far as the test on rodents may be taken as an indication, become so modified in its biological characters as the result of its treatment in bacteria beds or on land as to have altogether lost its potentially dangerous qualities.

I insist the more on this aspect of the question since it is constantly being urged, that in order to show the dangerous qualities of sewage effluents it is necessary to prove the presence in them of microbes pathogenic not only to the lower animals but also to human beings. With a view of illustrating the danger of accepting such contention as valid, I cite certain considerations that would seem parallel with those I have been advancing.

---

* These results are given in a separate report.

† It cannot be too strongly insisted on that sewage is not a substance *untried or unknown* in its relation to human disease. It has for long been an established fact that sewage can spread epidemic disease, and that this is due to the organisms contained in it. The only point open to doubt is how far effluents are to be thought of in the same sense. It is for this reason that so much work has been undertaken in the endeavour to trace the extent to which sewage becomes, while the total amount of bacteria in it is being reduced, *modified in its biological characters* by the different methods of sewage disposal at present in operation.

Thus all chemical methods of seeking to ascertain the truth in the analysis of water are indirect ones. That is, the chemist estimates the relative proportions of certain substances present in a water, not because they are themselves harmful but because he knows from previous experience that they are an index of that which is harmful. We now know that the harmfulness thus indicated is due for the most part if not wholly, to living organisms. For example, of two waters, the first containing ten times as much organic matter as the second, other things being equal, the former must be likely to contain ten times more objectionable microbes than the latter. Yet no one doubts that, despite these limitations, the chemical analysis of water has contributed in the past in no small measure to secure the purity of our water supplies. Why then demand from the bacteriologist information which the chemist is powerless to furnish ?

The remarkable progress made in preventive medicine when chemistry was in the ascendant and bacteriology was comparatively unknown, was largely due to the recognition that excremental matters are a source of danger to health. Not that it was believed by sanitarians (at all events of recent times) that a single drop of sewage or even a single sample in bulk must necessarily be possessed of disease-producing power. But all the observed facts pointed in one direction, namely, that excremental matters are always *potentially* dangerous ; that if not actually dangerous on all occasions some time or other they were pretty sure to be associated with, *i.e.*, to carry along with them, the virus of disease. For example, it has been observed again and again that a water supply continuously polluted with excremental matters may be drunk for long periods with impunity, and yet may sooner or later give rise to epidemic disease. We now know that this change from potential to actual danger depends on the ordinary comparatively harmless bacteria of excremental kind being sometimes accompanied by microbes, also of intestinal outcome, derived from a diseased source and possessed of and retaining definitely pathogenic properties. At the period referred to (as now) chemistry played a most useful part. It was found that whereas crude sewage was rich in organic matter, pure waters—waters removed from all sources of objectionable contamination—were almost free from organic matter. And this being so, sanitarians naturally viewed all waters containing an undue amount of organic matter with much suspicion. In brief, the *status* of a water from the health point of view was then (as now) largely judged by the proportion of organic matter present. And the wisdom of the teaching of the earlier sanitarians has received ample confirmation from the discoveries of bacteriologists. Obviously, apart altogether from the value of chemical and bacteriological researches, epidemiologists, on the *basis of observed facts*, were and are clearly justified in regarding sewage and, in general, excremental matters as *always* a likely source of danger to health.

Reverting to the biological aspects of sewage, bacteriologists at present cannot draw a reliable distinction between sewage containing the actual specific germs of disease and sewage free from all microbes of definitely pathogenic sort, and therefore, comparatively speaking, unobjectionable. But if we regard sewage as always potentially dangerous, and dangerous, moreover, not because it contains organic matter, but because it harbours microbes of intestinal sort, the great value of bacteriological tests of sewage becomes at once apparent. Sewage is a substance teeming with bacteria of intestinal outcome ; with bacteria, that is, absent, or relatively so, from pure water. It is only necessary then to determine the kinds of bacteria of intestinal origin present in sewage, and their *relative abundance*, to obtain a series of data of the utmost value—data which, in my opinion, yield information of a much more trustworthy kind than mere chemical facts.* Early

---

* Lest I be misunderstood, I must repeat the views I have already fully expressed to the Commission. In the case of drinking water streams, where the chief object is to guard against disease introduced into them by sewage, the bacteriological examination is of primary and the chemical examination is of secondary importance. But in the case of non-drinking water streams, where the main consideration is to avoid additions to the water of matters creating a serious nuisance, the converse holds good.

in 1898 a special research was carried out on these lines. Two microbes were selected, both typical of excremental matters, the one an aerobe (B. coli), and the other an anerobe (B. enteritidis sporogenes), and their *relative abundance* determined in multiple samples of sewage. Added to this, other lines of research bearing on the same subject were undertaken (e.g., as regards streptococci), but of these no special note need here be made. As the result of this work, it became possible to lay down certain bacteriological tests relating to crude sewage; to show the wide biological distinction between sewage and pure waters; to lay down a foundation for the subsequent examination of sewage effluents; and to enable a comparison to be drawn between sewage effluents and crude sewage as regards their probable degree of harmfulness. It was found that B. coli, B. enteritidis sporogenes, and streptococci ("microbes of indication")* were usually present in crude sewage in numbers exceeding 100,000, 100 to 1,000, and about 1,000 respectively per cc. As a contrast to these figures may be placed my experience as regards pure waters, namely, that these microbes are either altogether absent from them, or relatively so. With these records (previously lacking) made available, it became possible to judge the biological *status* of sewage effluents as regards their probable degree of harmfulness. The more nearly sewage effluents approached normal crude sewage standards the less could it be said that purification was satisfactory from the biological point of view, and the greater seemed to be their potential harmfulness. On the other hand, the fewer these "microbes of indication" were found to be, the more one felt justified in regarding such effluents as *relatively* safe.

To sum up, my propositions are briefly as follows:—

I have sought to show that sewage ought always to be regarded as a liquid potentially dangerous to health.

That sewage effluents which, so far as can be ascertained, resemble sewage in their biological composition ought also to be considered harmful; and that the inoculation of rodents is one way of obtaining information under this heading.

That there are tests available to the bacteriologist, which enable him to measure the degree to which an effluent agrees with or departs from normal crude sewage standards, and therefore to measure its probable degree of potential harmfulness, or, in other words, its *status* from the health point of view.

That it is not necessary to demonstrate in the effluent the presence of definitely pathogenic microbes to prove the element of danger. That on the contrary it is sufficient to show that bacteria indubitably of intestinal origin are present in an effluent to condemn it as potentially dangerous, for the reason that these micro-organisms are apt to be accompanied by bacteria well known to have caused disease in human beings.

[In much the same way, and in view of considerations broadly parallel, drinking-water has in the past been condemned (and rightly condemned) by the chemist because of undue presence in it of unoxidised organic matter, *not* by reason of any noxious quality ascertained to be bound up with the recognised adventitious material.]

II.—*The subcutaneous inoculation of guinea-pigs with crude sewage and effluents.*†

It has already been pointed out that that the subcutaneous injection of crude sewage into guinea-pigs nearly always produces a local reaction and not uncommonly death within a few days. Effluents naturally vary very

* "Microbes of indication" in the sense that these bacteria are intestinal germs apt to be associated with the pathogenic microbes which, by their occasional or frequent presence, may render sewage and sewage effluents actually dangerous.

† Unless otherwise stated, all the animals were inoculated subcutaneously in the groin.

much; while some equal crude sewage in their pathogenic qualities, others may be injected in large quantities without producing a fatal result. The effluents from land are usually less pathogenic than the effluents from bacteria-bed processes of sewage treatment. The following are examples both of pathogenic and of seemingly non-pathogenic, or at all events not markedly pathogenic samples.

Examples showing the pathogenic qualities of crude sewage and of effluents :—

Ducat's process at Hendon.—May 16, 1899.—20 cc. of the *effluent* were centrifugalised, 16 cc. were poured off, of the remaining 4 cc. mixed 2 cc. were used to inoculate a guinea-pig. The animal died on the 4th day.

Storm-water overflow. Altrincham Sewage Farm. April 29, 1900.—Two samples, 67 and 68; the former collected soon after the overflow had begun to work, the latter 1½ hours later. 2 cc. of each were severally injected subcutaneously into two guinea-pigs. Both died on the 3rd day.

Rugby. Street water from separate system after rain (96A).—June 20, 1900.—Two guinea-pigs were inoculated subcutaneously, the one (A) with 1 cc. the other (B) with 2 cc. Both had swollen bellies, but guinea-pig (A) eventually recovered. Guinea-pig (B) suffered from ulceration of the abdominal wall, and died on the 15th day.

S. Norwood. Street washings after running four hours.—Dec. 5, 1900.—Two guinea-pigs were inoculated subcutaneously, the one (A) with 1 cc. and the other (B) with 2 cc. of the sample. Although (A) guinea-pig eventually recovered it had a big swelling and was ill for some days. (B) guinea-pig died on the 2nd day.

Rugby. Street Washings during storm.—March 4, 1901.—A guinea-pig was inoculated subcutaneously with 4 cc. of the sample (231). It died on the 2nd day.

Rugby Sewage Farm.—March 7, 1901.—A guinea-pig was inoculated with 3 cc. of *crude sewage* (233). It died on the 2nd day.

Rugby Sewage Farm.—March 11, 1901.—A guinea-pig was inoculated with 2 cc. of *crude sewage* (235). It died on the 2nd day.

Exeter Septic tank effluent.—March 21, 1901.—A guinea-pig was inoculated subcutaneously with 2 cc. of sample. It died on the 4th day.

Luton Crude Sewage, 244A.—March 28, 1901.—A guinea-pig was inoculated subcutaneously with 3 cc. of the sample. It died on the 2nd day.

Ilford Crude Sewage.—August 27, 1901.—A guinea-pig was inoculated subcutaneously with 3 cc. of the sample. It died within 24 hours.

Ilford Crude Sewage.—September 6, 1901.—A guinea-pig was inoculated subcutaneously with 3 cc. of the sample. It died within 24 hours.

Examples showing that some effluents are not markedly pathogenic under the conditions of experiment :— *

Dibdin's process at Sutton.—June 29, 1899.—1 cc. of the *effluent* from a "fine bed" was injected subcutaneously into a guinea-pig. The animal recovered.

Leicester Sewage Farm.—Nov. 9, 1899.—2 cc. of the *final effluent* (No. 3) were injected subcutaneously into a guinea-pig. The animal recovered.

Leicester Sewage Farm.—Nov. 15, 1899.—2 cc. of the *final effluent* (No. 4), were injected subcutaneously into a guinea-pig. The animal recovered.

Nottingham Sewage Farm.—July 25, 1900.—A guinea-pig was inoculated subcutaneously with 4 cc. of *effluent* 111. There was no local reaction, and the animal was seemingly quite unaffected.

Nottingham Sewage Farm.—July 26, 1900.—A guinea-pig was inoculated subcutaneously with 8 cc. of *effluent* 113. It developed a big swelling and became quiet, but eventually recovered completely notwithstanding the large dose.

Beddington Sewage Farm.—Oct. 10, 1900.—Two guinea-pigs were inoculated subcutaneously the one with 1 cc. and the other with 4 cc. of *final effluent* 154. They were hardly, if at all affected, and both recovered completely.

South Norwood Sewage Farm.—Nov. 20, 1900.—Two guinea-pigs were inoculated subcutaneously, the one (A) with 1 cc. of *settled sewage* 176, the other (B) with 4 cc. of *final effluent* 178. (A) guinea-pig had a slight thickening at the site of the inoculation, but otherwise remained unaffected. (B) guinea-pig showed little or no reaction.

Rugby Sewage Farm.—February 18, 1901.—A guinea-pig was inoculated subcutaneously with 4 cc. of *effluent* 225. There was hardly any local reaction and the animal recovered completely.

Rugby Sewage Farm.—February 27, 1901.—A guinea-pig was inoculated subcutaneously with 10 cc. of *effluent* 230. The animal was seemingly but slightly affected. Fourteen days later it died, but on examination the organs seemed healthy (beyond some slight congestion of the lungs), and it is probable that death was not directly due to the effects of the injection

Rugby Sewage Farm.—March 5, 1901.—A guinea-pig was inoculated subcutaneously with 10 cc. of *effluent* 232. The animal was seemlingy unaffected and remained quite well for several weeks.

* Possibly some of the experiments included in this column may be considered to belong more properly to the left column or else to a separate column, standing as regards pathogenicity mid-way between the two.

S. Norwood settled Sewage (sample A).—September 10, 1901.—A guinea-pig was inoculated subcutaneously with 3 cc. of the sample. It died within 24 hours.

S. Norwood settled Sewage (sample D).—September 11, 1901.—A guinea-pig was inoculated subcutaneously with 3 cc. of the sample. It died within 24 hours.

S. Norwood settled Sewage (sample G).—September 12, 1901.—A guinea-pig was inoculated subcutaneously with 3 cc. of the sample. It died within 24 hours.

S. Norwood 1st field effluent (B).—September 10, 1901.—Two guinea-pigs were inoculated subcutaneously, one with 3 cc. and the other with 6 cc. of the sample. Both died within 3 days.

S. Norwood 1st field effluent (E).—September 11, 1901.—Two guinea-pigs were inoculated subcutaneously, one with 3 cc. and the other with 6 cc. of the sample. Both died within 2 days.

Rugby Sewage Farm.—March 6, 1901.—A guinea-pig was inoculated subcutaneously with 10 cc. of *effluent* 234. It was apparently unaffected and remained well for 24 days. It was then killed and examined; the organs were normal in appearance, but a small abscess was found at the seat of the inoculation.

Rugby Sewage Farm.—March 11, 1901.—A guinea-pig was inoculated with 10 cc. of *effluent* 237. It was but slightly, if at all affected, and remained well for several weeks.

Aldershot.—July 2, 1901.—*Street washings* during storm.—A guinea-pig was inoculated subcutaneously with 1 cc. of sample (311), There was some local reaction, but the animal eventually recovered completely from the effects of the injection.

Aldershot.—July 3, 1901.—*Street washings* during storm. A guinea-pig was inoculated subcutaneously with 2 cc. of sample (314). A localised swelling developed, but the animal eventually recovered completely from the effects of the injection.

S. Norwood 1st field effluent (H).—Collected during rainy weather.—September 12, 1901.—In this experiment guinea-pigs inoculated with 3 and 6 cc. of the sample recovered.

S. Norwood final effluents (C, F, & I).—Collected respectively on September 10, 11, and 12, 1901.—In each case two guinea-pigs were inoculated, one with 3 cc. and the other with 6 cc. of the sample. The animals, however, all recovered from the effects of the injections.

From the results of these experiments it is obvious that crude sewage is usually for rodents a highly pathogenic liquid. Further, that "street washings," storm water overflow liquid from sewage works, and bad effluents are also apt to be fatal on subcutaneous injection into guinea-pigs. Lastly, that some sewage effluents may be injected into these animals in relatively large amount without producing a pathogenic result.* Land effluents, so far as observed, are usually less pathogenic to rodents than effluents from bacteria-bed processes of sewage disposal.

III.—*The Subcutaneous inoculation of Guinea-pigs with crude sewage previously heated to* 80° *C. for ten minutes.*

As already indicated, if sewage be heated to 80° for ten minutes a pathogenic result may still be produced, but usually a larger dose of the liquid is required, and death is not so quickly induced.

The following experiments exemplify these facts:—

(1) *Rugby Sewage Farm*, February 18, 1901.—Some settled sewage (224) was heated to 80° C. for ten minutes, and then 4 cc. were injected subcutaneously into a guinea-pig. A slight swelling developed at the site of the inoculation, but the animal recovered completely.

(2) *Rugby Sewage Farm*, March 6, 1901.—Some crude sewage (233) was heated to 80° C. for ten minutes, and then 6 cc. were injected subcutaneously into a guinea-pig. The animal remained apparently unaffected. Half the dose (*not heated*) killed another guinea-pig in two days.

---

* This latter circumstance must not be considered to yield any proof that such effluents are free from the presence of undesirable microbes. The test, indeed, is not a delicate one since effluents yielding unequivocal evidence by other methods of the presence of objectionable bacteria may yet yield on inoculation into rodents negative results. As regards many of the samples under scrutiny other biological data are available. These parallel observations are of such a nature as to lead to the conclusion that effluents in general do not give rise to an appreciable pathogenic effect on inoculation into rodents unless the number of undesirable microbes (*e.g.*, B. Coli) present in them run into hundreds or even thousands per c.c. and most certainly into figures which no responsible bacteriologist could accept as safe in the case of the discharge of an effluent into a drinking water stream, even if the dilution of the effluent with river water was much above the [illegible]rage.

(3) *Rugby Sewage Farm*, March 11, 1901.—Some crude sewage (235) was heated to 80° C. for ten minutes, and then 8 cc. were injected subcutaneously into a guinea-pig. The dose proved too large, and the animal died on the second day, notwithstanding the preliminary heating of the sewage.

(4) *Ilford Crude Sewage*, August 28, 1901.—Some of the sewage was heated to 80° C. for ten minutes, and then 5 cc. were injected subcutaneously into a guinea-pig. The animal showed some local reaction, but twelve days later was alive and well. 3 cc. of the same sample (*not heated*) killed another guinea-pig within twenty-four hours.

(5) *Ilford Crude Sewage*, September 6, 1901.—Some of the sewage was heated to 80° C. for ten minutes, and then 6 cc. were injected subcutaneously into a guinea-pig. The dose proved too large, the animal dying on the third day. 3 cc. of the same sample (*not heated*) killed another guinea-pig within twenty-four hours.

(6) *S. Norwood Settled Sewage*, sample A, September 10, 1901.—Same conditions of experiment as in experiment 5, but 5 cc. used for the injection. The animal recovered. 3 cc. of the same sample (*not heated*) killed another guinea-pig within twenty-four hours.

(7) *S. Norwood Settled Sewage*, sample D, September 11, 1901.—Same conditions of experiment as in experiment 6, and with same negative result. But 3 cc. of the same sample (*not heated*) killed another guinea-pig within 24 hours.

(8) *S. Norwood Settled Sewage*, sample G, September 12, 1901.—In this experiment 5 cc. proved fatal (second day), while 3 cc. of the same sample (*not heated*) killed another guinea-pig within 24 hours.

These experiments show that sewage, after being heated to 80° C. for ten minutes (this temperature would destroy bacilli, but not the spores of bacilli), is less pathogenic than sewage *not heated*, but that a fatal result may still be produced if the amount injected into the guinea-pigs be sufficiently great. Death, when it does occur, is usually less early with the *heated* than with the *not heated* sewage.

IV.—*The Subcutaneous Inoculation of Guinea-pigs with Crude Sewage previously heated to* 100° *C.*

It has already been said that if crude sewage be previously heated to 100° C. for 1 hour, large quantities may be injected without producing a fatal result. The following experiments serve as examples :—

(1) *Hendon Crude Sewage*, May 16, 1899.—Some of the sewage was heated to 100° C. for 1½ hours and 4 cc. were injected subcutaneously into a guinea-pig. The animal seemed rather quiet for the first day or two, but eventually recovered completely.

(2) *Ilford Crude Sewage*, August 27, 1901.—Some of the sewage was heated to 100° C. for one hour and 7 cc. were injected subcutaneously into a guinea-pig. The animal showed a slight local reaction, but twelve days later was seemingly quite well.

(3) *Ilford Crude Sewage*, September 6, 1901.—Some of the sewage was heated to 100° C. for one hour, and 10 cc. were injected subcutaneously into a guinea-pig. The animal seemed to be little, if at all, affected, and twelve days later was found to be quite lively and well.

(4) *S. Norwood Settled Sewage*, September 10, 1901. Sample A.—The experiment was carried out on exactly the same lines as recorded under experiment 3, and with the same negative result.

(5) *S. Norwood Settled Sewage*, September 11, 1901, Sample D.—Same negative result as A, experiment 4, under the same conditions of experiment, and with the same dose.

(6) *S. Norwood Settled Sewage*, September 12, 1901, Sample G.—Same negative result as A, experiment 4, under the same conditions of experiment, and with the same dose.

As regards experiments 2, 3, 4, 5, 6, three cc. of the same samples (*not heated*) in each case killed guinea-pigs within 24 hours.

The results of these experiments show that a three-fold lethal dose of sewage after preliminary heating to 100 deg. C. for 1 hour either produces no apparent effect on injection, or only a slight local reaction.

V.—*The Subcutaneous Inoculation of Guinea-pigs with Crude Sewage after preliminary treatment as follows :—*

(a) *Heated to* 65° *C. for* 20 *minutes, and rendered germ-free by filtration through a sterilised Pasteur filter.*

(b) *Heated to* 80° *C. for* 10 *minutes, and rendered germ-free by filtration through a sterilised Pasteur filter.*

(c) *Heated to* 100° *C. for* 1 *hour, and rendered germ-free by filtration through a sterilised Pasteur filter.*

(1) *Nottingham Crude Sewage*, September 26, 1901.—Three guinea-pigs (*a*, *b*, *c*), were inoculated each with 20 cc. of the filtered liquid under (a), (b), and (c) set of conditions. The animals were seemingly but little, if at all, affected by the injections, and remained lively and well*.

(2) *Leicester Crude Sewage*, October 12, 1901.—Experiment (1) was repeated, but Leicester, instead of Nottingham crude sewage, was used. The results were negative as in experiment (1).

These experiments seem to show that heating sewage under the above conditions of experiment does not set free any soluble poisons in such amount as to be capable of producing any appreciable pathogenic result when the filtered liquid is injected in large dose into rodents.

It has already been noted that sewage heated to 80° C. for 10 minutes remains in the *unfiltered* condition a liquid still possessed of pathogenic qualities, although a larger dose is required to produce a pathogenic result than when the liquid has not been so heated. From the results of the above experiments under (b) set of conditions it is obvious that the pathogenic qualities are not to be attributed merely to the heating setting free soluble poisons but to the vital activity of microbes present in the sewage in the form of spores.

VI.—*The Subcutaneous Inoculation of Guinea-pigs with Crude Sewage previously filtered through a Sterilised Pasteur's Filter.*

As previously explained, if crude sewage be filtered through a Pasteur filter, large doses of the filtrate may be injected into guinea-pigs without producing a fatal result. The following experiments may be cited in illustration of the truth of this observation :—

(1) *Hendon Crude Sewage*, May 16, 1899.—Some of the sewage was filtered through a sterilised Pasteur's filter, and then 4 cc. of the filtrate were injected into a guinea-pig. The animal remained seemingly quite unaffected.

(2) *Luton Crude Sewage*, March 27, 1901.—Some of the sewage (244A) was filtered through a sterilised Pasteur's filter, and then 20 cc. of the filtrate were injected subcutaneously into a guinea-pig. The animal remained apparently unaffected. Another guinea-pig inoculated with 3 cc. of the unfiltered sewage died on the second day.

(3) *Ilford Crude Sewage*, August 27, 1901.—Some of the sewage was filtered through a sterilised Pasteur's filter, and then 20 cc. of the filtrate were injected subcutaneously into a guinea-pig. The animal remained apparently unaffected.

(4) *Ilford Crude Sewage*, September 6, 1901.—Some of the sewage was filtered through a sterilised Pasteur's filter, and then 20 c.c. of the filtrate were injected subcutaneously into a guinea-pig. The animal remained apparently unaffected.

(5) *S. Norwood Settled Sewage*, Sample A, September 10.—The experiment was carried out under the same conditions as in Experiment 4, and with the same negative result.

(6) *S. Norwood Settled Sewage*, Sample D, September 11, 1901.—Same conditions of experiment as in Experiment 4, with the same negative result.

(7) *S. Norwood Settled Sewage*, Sample G, September 12, 1901.—Same conditions of experiment as in Experiment 4, with the same negative result.

(8) *S. Norwood Settled Sewage*, Sample J, September 18, 1901.—Same conditions of experiment as in Experiment 4, with the same negative result.

(9) *Nottingham Crude Sewage*, September 26, 1901.—Same conditions of experiment as in Experiment 4, with the same negative result.

(10) *Leicester Crude Sewage*, October 12, 1901.—Same conditions of experiment as in Experiment 4, with the same negative result.

As regards experiments 3, 4, 5, 6, 7, 8, three cc. of the same samples(*unfiltered*) proved in each case fatal on injection into guinea-pigs within 24 hours.

These experiments show that large doses of sewage rendered germ-free by filtration are seemingly innocuous when injected into guinea-pigs. Apparently about seven times an otherwise lethal dose of sewage may be injected in this manner without producing any very appreciable result.

---

* In a previous experiment with S. Norwood crude sewage the liquid treated under (a) set of conditions did produce a pathogenic result. The animal died on the third day, and on examination showed thickening of the abdominal wall, intense congestion, and sanguineous exudation. In view of the wholly negative result obtained with Nottingham and Leicester sewage, it is probable that some additional factor must have intervened in this case.

VII.—*The Microbes Concerned in producing the Pathogenic Results.*

In a separate report the presence of anthrax in the septic tank and bacterial beds at Yeovil has been fully considered. In the present report the presence of B. pseudo-tuberculosis in some sewage effluent is dealt with.* But it is highly probable that as regards rodents the pathogenic qualities of sewage and sewage effluents are due to the vital activity of a large number of different microbes, some aerobic, others anaerobic; some spore-forming, others non-spore-forming. Further, that the pathogenic result is likely in most cases to be due to a mixed infection; that is, infection due to pathogenic bacteria of more than one sort acting concurrently.

In the case of those samples, previously heated to 80° C. for ten minutes, which, nevertheless, exercised a pathogenic effect when injected in gross amount, it is evident that the microbes at fault must have been spore-forming ones. It is not improbable that these may belong to the malignant œdema class of microbes, and possibly also B. enteritidis sporogenes may be concerned in producing the fatal result. But as has been already explained, the pathogenic action of sewage and effluents would seem to be principally due to the bacteria present as bacilli, not as spores, because a much smaller dose of sewage suffices to kill a guinea-pig when the liquid has not been previously heated to 80° C., and also death takes place, as a rule, more speedily.

As regards those samples (not previously heated to 80° C.) which proved fatal on injection into guinea-pigs, a number of microbes have been isolated from the blood and other tissues of the animal after death, some belonging to the B. coli class, others to the B. proteus group, yet others again to species which could not be identified.† Most of these microbes, when injected in pure culture into guinea-pigs, proved highly virulent. But as regards B. coli, at all events, there is always the possibility that the microbe isolated from the dead animal may not have really been derived from the sewage at all, but from the animal itself—that, in short, it may have been a strain of B. coli which had passed through the intestinal wall of the experimental animal and invaded the organs and tissues owing to their diminished resistance consequent on the injurious effects of the injection and the vital activity of the bacteria introduced with the material used for inoculation purposes. Even if this were not the case, the virulent character of the B. coli thus isolated may in reality be a property wholly or in part foreign to the B. coli introduced with the sewage; that is, the virulent character may conceivably be a property acquired during its temporary sojourn in the body of the animal, and the death of the animal may result largely, if not entirely, from the action of bacteria of different sort altogether. These are questions difficult, indeed almost impossible at the present time, to decide in a satisfactory manner. Nevertheless, if a guinea-pig succumbs within a few days after inoculation with sewage (a liquid known to be teeming with B. coli), if it be examined immediately after death, and if the predominant microbe isolated from the blood, tissues, or site of the wound is proved to be a highly virulent strain of B. coli, the inference is in favour of this microbe having been concerned in the infective process.

The whole subject merits further investigation, but the pressure of other work for the Commission—work likely to yield more immediately useful results—has prevented me so far from carrying out a more comprehensive research.

---

* Two other microbes pathogenic alike to man and animals met with in my previous investigations may be mentioned. In one case a guinea-pig inoculated with a small quantity of the deposit collecting on the material composing a bacterial bed died of true tuberculosis (Koch's B. tuberculosis). In another instance two mice inoculated with the deposit from another bacterial bed died of tetanus (lockjaw).

† In one instance B. pyocyaneus was isolated from the heart's blood of a guinea-pig which had died after inoculation with 3 cc. of S. Norwood first field effluent B, September 10, 1901.

In conclusion, a single example may be given in illustration of this class of work :—

Exeter Septic Tank Effluent, March 21, 1901.—A guinea-pig was inoculated subcutaneously with 2 cc. of the liquid. It died on the fourth day. Cultures made from the heart's blood yielded a strain of B. coli, giving the following characters :—"Gas" in gelatine "shake" culture in 24 hours at 20° C. Diffuse cloudiness in broth cultures (at 37° C.) in 24 hours and indol on the fifth day. Strong acid and solid clot in litmus milk cultures (at 37° C.). $\frac{1}{8}$ cc. of a broth culture (24 hours at 37° C.) was injected subcutaneously into a guinea-pig. The animal died on the second day.

VIII.—*Pseudo-Tuberculosis.*

(*B. Pseudo-tuberculosis of A. Pfeiffer.*)*

As early in the work for the Commission as May, 1899, it was found that sewage effluents may contain B. pseudo-tuberculosis; and since then this pathogenic microbe has been found on more than one occasion to be present in the effluents from different processes of sewage purification. That it has not been found more often is probably due to the fact that animals inoculated with sewage effluents are apt to die before the slow B. pseudo-tuberculosis process of infection has been given an opportunity of developing. Further, even in those cases in which the animal recovers from the *primary* effects of the inoculation it is possible that the reaction at the seat of the inoculation produced by the numerous other microbes present may suffice to destroy there, the vitality of the B. pseudo-tuberculosis.

I.—*Ducat's Process.* May 2, 1899. Two cc. of the *effluent* from Ducat's filter at Hendon were inoculated subcutaneously into a guinea-pig. The animal died on the twentieth day from pseudo-tuberculosis. Fig. 1.

II.—*Dibdin's Process.* June 22, 1899. One cc. of the *effluent* from one of the secondary (fine material) bacterial contact beds at Sutton was injected subcutaneously into a guinea-pig. The animal died from pseudo-tuberculosis.

III.—*Nottingham Land Process.* December 6, 1899. Three cc. of *effluent* (No. 12) were injected subcutaneously into a guinea-pig. The animal died on the 30th day from pseudo-tuberculosis.

IV.—*Rugby Crude Sewage.* February 19, 1901. Two cc. of *crude sewage* (No. 224) were injected subcutaneously into a guinea-pig. The animal died on the 26th day from pseudo-tuberculosis. Figs. 2, 3, 4.

V.—*Exeter septic tank effluent.* March 21, 1901. Two cc. of septic tank *effluent* were injected subcutaneously into a guinea-pig. The animal died on the 19th day from pseudo-tuberculosis. Fig. 5.

It must not be concluded from these experiments that an effluent giving rise to pseudo-tuberculosis is *necessarily* a bad one. Quite the contrary may be the case. For example, in Experiment I. the effluent was a particularly good one.†

The real importance of these results lies in the fact that B. pseudo-tuberculosis is not only pathogenic to the lower animals, but also, it would seem, to human beings. It is true that the disease is believed to be a very rare one, but it is not impossible that the affection may in reality be less uncommon

---

* Pseudo-tuberculosis (B. pseudo-tuberculosis of Pfeiffer), figures 1 to 5, must not be confused with true tuberculosis (tubercle bacillus of Koch), although the two diseases have many features in common (*e.g.*, the chronic nature of both affections, the occurrence of nodular deposits in various organs, etc.). Incidentally, however, it is of interest to note that on a single occasion a guinea-pig was successfully infected with true tuberculosis, the material in this case being the deposit collecting on the coke in a bacterial bed.

† That is, "good" for a sewage effluent, not "good" in the sense of being fit for domestic use.

than is at present supposed. In a recent report to the Local Government Board, Dr. Klein, speaking of the discovery by him that a by no means inconsiderable percentage of milk samples contains B. pseudo-tuberculosis, says: "I think it is not too much to say that the presence of the bacillus of pseudo-tuberculosis in milk may probably play a part in causing pseudo-tuberculous disease in the human subject."

It is noteworthy that pseudo-tuberculosis differs from many of the microbic affections that I have been dealing with in that it is one of the few diseases that can *readily* be transmitted to the lower animals by *feeding* experiments. Guinea-pigs fed on a *single* occasion with food material contaminated with B. pseudo-tuberculosis are apt to develop pseudo-tuberculosis.

The following is a description of the chief morphological and biological characters of B. pseudo-tuberculosis :—

B. PSEUDO-TUBERCULOSIS.*

Source.—Isolated from the spleen of a guinea-pig which died of pseudo-tuberculosis resulting from inoculation with Rugby settled sewage. Other strains of B. pseudo-tuberculosis obtained from the organs of guinea-pigs which had died of pseudo-tuberculosis after the injection of Exeter tank effluent, Dibdin's bacteria bed effluent at Sutton, etc., resembled this one in every respect.

Morphology.—Resembles B. coli somewhat closely. Short small bacilli occurring singly, in couples and short chains, with here and there a filamentous form. In broth culture the appearance is much more characteristic. Here, at first sight, one might almost be led to consider the microbe as a streptococcus, but on closer inspection it will be seen that the chains are composed, not of cocci, but short bacilli. This characteristic appearance is best observed in unstained preparations. In stained specimens the chain formation is much less noticeable. Figs. 2 and 3.

Motility.—Usually stated to be non-motile. Certainly most of the elements are non-motile, but it may be questioned if a few of them do not possess some degree of spontaneous motion.

Gelatine and agar plate cultures (20° C. and 37° C. respectively).—The growth resembles B. coli very closely, but the colonies tend to be more circumscribed and granular looking, and later they may present a tuberculated appearance, and show also some concentric ringing. The growth is also rather slower than B. coli, and the colonies have a more opaque and less filmy appearance. Nevertheless, the resemblance is a striking one.

Gelatine and agar oblique culture (20° C. and 37° C. respectively).—The growth resembles B. coli, but is more limited in extent, and is slower. The character of the growth is more opaque and less filmy than B. coli, and may show after some time a tuberculated appearance. Figs. 4 and 5.

Gelatine "shake" culture (20° C.).—No "gas" is formed, growth occurs throughout the tube.

Broth cultures (37° C.).—The growth is characteristic. In twenty-four hours there is diffuse cloudiness, but also well-marked granular cloudiness, and small flocculi are seen floating throughout the liquid.

Litmus milk cultures (37° C.).—For one or several days there is no visible change. Later, a trace of alkali appears, and the alkaline change becomes daily more decided until it is striking and unmistakable.

Animal experiments.—Guinea-pigs inoculated subcutaneously with a small amount of a culture die within a few weeks. Their organs are found to be studded with yellowish white nodules, containing B. pseudo-tuberculosis in pure culture. Figs. 1 and 5. Guinea-pigs fed with food contaminated with a culture of B. pseudo-tuberculosis die somewhat more quickly, and nodular deposits may readily be seen in the walls of the small intestine and in the mesenteric glands.

IX.—*B. Pyocyaneus in Crude Sewage and Effluents*†.

In the London County Council Experiments (1898-9) B. pyocyaneus was on rare occasions found in the crude sewage and effluents from the bacteria beds. Since then a careful look-out has been kept for this pathogenic microbe, but it has not been found to be present in crude sewage and sewage effluents except in rare cases. But it is quite possible that it may often have escaped notice owing to the enormous number of other bacteria present in the cultures. B. pyocyaneus is a microbe of virulent sort in the

* In a recent report to the Local Government Board Dr. Klein gives an exhaustive account of the morphological and biological characters of B. pseudo-tuberculosis.

† It is convenient to include these results in this Report, although perhaps, strictly speaking, they ought to come under a separate category

case of rodents, and it is not uncommonly found to be associated with other pyogenic bacteria in abscesses (bacillus of green pus) and other morbid processes occurring in the human subject. B. pyocyaneus is a chromogenic microbe, producing in various media a characteristic fluorescent green colouration. It differs from the ordinary liquefying fluorescent bacteria (B. fluorescens liquefaciens and its allies) so commonly met with in water, soil and sewage cultivations in a number of important respects. For example, the ordinary liquefying fluorescent bacteria as a rule grow feebly or not at all at blood heat, are not pathogenic, and do not give rise to the same tint of green in culture media. B. pyocyaneus on the other hand, grows luxuriantly at blood heat and produces at that temperature, as well as at lower temperatures, a characteristic dark olive green colouration in agar cultivations. Moreover, if 0·5 cc. (a much smaller amount may suffice) of a 24 hours broth culture (at 37°C.) be injected subcutaneously into a guinea-pig, the animal dies usually in less than 24 hours, and a cultivation made from its heart's blood yields B. pyocyaneus in pure culture.

The following is a brief account of the work done in this direction :—

Experiment 1, *Hendon Crude Sewage*, May 31, 1899.—B. pyocaneus present in $\frac{1}{100000}$ cc.. On 0·5 c.c. of a 24 hrs. broth culture of this microbe being injected subcutaneously into a guinea-pig, the animal died within 24 hrs. B. pyocyaneus was recovered from the heart's blood in pure culture.

Experiment 2, *Ducat's bacteria bed effluent corresponding* to crude sewage, Experiment 1, May 31, 1899.—B. pyocyaneus present in $\frac{1}{2000}$ cc. On 0·5 cc. of a 24 hrs. broth culture being injected subcutaneously into a guinea-pig, the animal died within 24 hrs. B. pyocyaneus was recovered from the heart's blood in pure culture. *See* Fig. 6.

Experiments 1 and 2 are of special interest. Dr. Gordon carefully determined the number of B. pyocyaneus in the crude sewage and in the effluent. The reduction number in the effluent was 98 per cent. The total number of bacteria (agar at 37° C.), in the crude sewage and effluent was respectively 3,070,000 and 77,000 per cc., a reduction of over 97 per cent. Here then we have a remarkable instance of a particular microbe, and moreover a pathogenic one, present in the crude sewage, being reduced in almost exactly the same proportion as the total number of microbes was reduced by the bacteria bed treatment of the sewage.

The question is frequently asked—are the microbes appearing in a particular sample of effluent *corresponding* to a particular sample of sewage, simply the bacteria contributed along with that sewage and which have passed the barrier of the bacteria bed ; or are they the progeny of these same bacteria ; or, lastly, are they microbes related to sewage reaching the bed days, or even weeks beforehand ? The subject is a most intricate one, but it seems reasonable to suppose that in a bacteria bed there are processes leading to loss of vitality as well as conditions favouring multiplication ; that although many of the microbes present in the crude sewage pass directly through the bed, some are retained, and that there is a constant washing out of some of the bacteria held back in the bed and related to previous samples of crude sewage. In this view of the case the bacteria in a particular effluent represent for the most part the bacteria of the *corresponding* sample of crude sewage, together with some microbes washed out of the bed, which really belong to past samples of sewage. The matter is complicated by the possibility or probability of microbes of different species behaving in a quite different fashion during the process. In the case of a bactoria bed yielding uniformly an effluent containing much fewer bacteria than the crude sewage, we must assume either that the bacteria are mechanically held back and gradually accumulate until the bed chokes,* or else that a stage is reached in the history of a bed when the rate of decay of bacterial life in the bed is equivalent to the observed percentage reduction in the number of micro-organisms in the effluent as compared with the crude sewage. The subject is one of great importance, because if it could be shown that the bacteria in a particular effluent were not. for the most part, related to the bacteria in the *corresponding* sample of sewage, but were derived from the storage in the bed of the micro-organisms of much earlier samples of crude sewage, it might be contended that this circumstance was in favour of the possibility of pathogenic microbes being destroyed or their virulence inhibited in the process. But it is greatly to be feared that the bulk of bacteria in a particular effluent bears a direct relation to the bacteria in the *corresponding* sewage, and experiments 1 and 2 seem to favour this view. For the crude sewage contained 3,070,000 bacteria and 100,000 B. pyocyaneus, and the effluent 77,000 bacteria and 2,000 B. pyocyaneus per cc., a percentage reduction of 97 and 98 respectively. It must be remembered that B. pyocyaneus is only rarely met with in sewage and sewage effluents, so that the 2,000 B. pyocyaneus in the effluent were directly related to the 100,000 in the corresponding sample of crude sewage hardly admits of any doubt.

The plain facts of the case are sufficiently striking, namely, that a pathogenic microbe was present in the effluent in exactly the same proportion relative to the total bacterial flora as in the crude sewage.

---

* Possibly during storms, when the volume of sewage becomes much increased, the bacteria in the case of "continuous flow" beds are "washed out" in great numbers.

It must not be supposed that because an effluent contains B. pyocyaneus it is necessarily worse than other effluents in which B. pyocyaneus cannot be found. In the present case the effluent under consideration showed a high percentage degree of biological purification, and, moreover, B. pyocyaneus is seldom met with in crude sewage. The lesson to be learnt is obvious, namely, that the results of the above experiments form a link in the chain of evidence which goes far to prove that the effluents from bacterial beds cannot reasonably be assumed to be uniformly more safe (except, perhaps, as regards *amount* of undesirable microbes) than sewage.*

Experiment 3.—*Croydon Sewage Farm, effluent* 23, January 10, 1900.—B. pyocyaneus present in 1 c.c. 0·5 cc. of a twenty-four hours broth culture injected subcutaneously into a guinea-pig. The animal died within twenty-four hours. B. pyocyaneus was recovered from the heart's blood in pure culture.

Experiment 4.—*Rugby Sewage Farm, crude sewage* 93, June 20, 1900.—B. pyocyaneus (? variety) present in $\frac{1}{100}$ cc. 0·5 cc. of a twenty-four hours broth culture was injected subcutaneously into a guinea-pig. The animal died within twenty-four hours. The same microbe was recovered from the heart's blood in pure culture. This microbe differed somewhat from the typical B. pyocyaneus, inasmuch as the green colour produced in agar cultures was of a paler tint than normal.

Experiment 5.—*Ducat's Filter Effluent at Hendon*, July 18, 1900.—A microbe (? variety of B. pyocyaneus) was present in 1 cc., which seemed at first to be typical of B. pyocyaneus. But it was not virulent in broth culture, hardly even feebly pathogenic.

Experiment 6.—*Leicester Sewage Farm, effluent* 137, September 12, 1900.—B. pyocyaneus present in $\frac{1}{10}$ cc. 0·5 cc. of a twenty-four hours broth culture injected subcutaneously into a guinea-pig. The animal died within twenty-four hours. B. pyocyaneus was recovered from the heart's blood in pure culture.

Expesiment 7.—*S. Norwood Sewage Farm, effluent from first field*, September 10, 1901.—Sample B.—This experiment differed from the preceding inasmuch as B. pyocyaneus was isolated from the animal after inoculation with the effluent. 3 cc. of the effluent were injected subcutaneously into a guinea-pig. The animal died on the third day, and from its heart's blood a pure culture of B. pyocyaneus was obtained.

X.—*Summary.*

In general summary of the foregoing results the following points seem worthy of note :—

(1) The subcutaneous injection of crude sewage into guinea-pigs (about 1—3 cc. per 200 grammes body weight) always produces a local reaction and not uncommonly death within 24—72 hours.

(2) "Street washings," storm-water overflow liquid from sewage works, and in general bad effluents, are also apt to be pathogenic under the above conditions of experiment.

(3) Good effluents may be injected in relatively large amount without producing a fatal result.

(4) Land effluents, in my experience, are usually less pathogenic than effluents from bacteria-bed processes of sewage disposal.

(5) If sewage or effluents be previously heated to 80° C. for 10 minutes a pathogenic result may still be produced, but usually a much larger dose of the liquid is required.

(6) If sewage or effluents be previously heated to 100° C. for one hour large doses of the liquid fail to produce a pathogenic effect.

---

* The question of dose or amount of morbific poison is not forgotten. This consideration and others of similar sort must needs, in the future, be brought to bear on the subject when it is considered in a broad and general way and when all the chemical and bacteriological records are available. In the meantime I am largely considering effluents by themselves, apart from controlling influences, which, it is to be feared, despite their importance, are not easily capable of estimation or expression either in general or particular cases.

(7) Sewage rendered germ-free by filtration through a sterilised Pasteur filter may be injected into guinea-pigs in large amount without producing any appreciable result. Preliminary heating of the sewage to (*a*) 65° C. for 20 minutes, (*b*) 80° C. for 10 minutes, (*c*) 100° C. for one hour does not seem to affect this negative result.

(8) Some samples of sewage and effluent contain B. *pseudo-tuberculosis* and some B. *pyocyaneus*. Both these microbes are highly pathogenic to lower animals, and are also related to morbid processes occurring in the human subject.

XI.—*Conclusions.*

To apply the results obtained by the subcutaneous inoculation of the lower animals with sewage and with effluents *too closely* to the conditions affecting or likely to affect human beings would be obviously injudicious. But the results as a whole lend themselves to certain inferences even if these be only regarded as of a provisional kind.

In the first place, the pathogenic qualities of most sewage effluents under the conditions of the experiments point to the improbability of sewage being so modified in its biological characters by treatment on land or by artificial processes as to be other than a liquid relatively still potentially dangerous to human beings. The absence of a definitely pathogenic result on rodents in the case of some sewage effluents is in all likelihood and in most cases merely an indication of their comparative not their absolute harmlessness to these animals.*

Secondly, the absence of any pathogenic result when sewage (heated or unheated) is rendered germ-free by adequate filtration is to some extent reassuring as tending to show that the chemical products of the vital activity of the bacteria in sewage are not of a markedly poisonous nature. That is, non-poisonous under the condition of experiment and in the case of rodents. It does not necessarily follow that the filtered sewage would be altogether harmless if drunk by human beings, however probable this may seem to be.

Thirdly, it is of interest to note that although the bacteria present as *bacilli* were most active in producing a pathogenic result, the microbes present as *spores* were also virulent, provided the dose employed was sufficiently large.

Fourthly, the presence of B. *pseudo-tuberculosis* and B. *pyocyaneus* in some sewage effluents is important in view of the fact that these microbes have been found to be related to morbid processes occurring in the human subject. It may, moreover, be of significance in relation to human disease that the former microbe is fatal to rodents when mixed with their food.

---

* It is, however, not inferred that because an effluent is fatal when inoculated into rodents it is necessarily dangerous if drunk by human beings. The contention is that untreated sewage must from past experience be accepted as a potentially dangerous liquid in relation to human disease, and that the inoculation of rodents is merely a way of testing how far sewage has become modified in its biological characters as the result of treatment on land or in bacteria-beds. If effluents equally with crude sewage are found to be pathogenic to rodents, then we may risk the assertion that, as no modification is apparent as regards rodents, it would be wise to regard such effluents in the same category as crude sewage in relation to potential danger to human beings. The important question of dilution is not lost sight of. But, as a starting point, it is desirable to consider effluents in the abstract sense, unfettered by attention to factors which must needs vary in different cases, and also in individual cases, from time to time. Questions of dilution, &c., may, and indeed should, in my opinion, be subsequently brought to bear on the subject by way of modifying or correcting provisional inferences. Nevertheless, I would urge that questions of dilution, percentage purification, and the like, are of more importance from the chemical than the biological point of view. Mere dilution, apart from biological modification is a dangerous element to rely on. The history, for example, of "water epidemics" would not seem to place a high value, if I may so express it, on dilution, unaccompanied by any other restraining influence.

Lastly, these conclusions must be interpreted in a relative sense. The admittedly artificial character of my experiments and the fact that I have dealt with effluents by themselves and not effluents diluted and altered by mixture with river water and exposed to other conditions of a sort likely to restrain or destroy their pathogenic qualities may, I think, reasonably be adduced as arguments against accepting without qualification even the cautious inferences that I have tentatively advanced.

EXPERIMENTS ON THE LONGEVITY OF THE BACILLUS TYPHOSUS IN SEWAGE AND SEWAGE EFFLUENTS.

By Alfred MacConkey.

Reasons for the Investigation.

It having been shown that the final effluent from the various biological methods of sewage treatment very often contained the B. coli in large numbers; in other words that not all the intestinal parasites which left the alimentary tract of man and animals were got rid of in the methods employed, the question naturally has occurred whether if the bacillus of typhoid fever found its way into bacterial beds it would survive and pass into the effluent, and so constitute a danger.

In the series of experiments upon the effect of filtration on sewage effluents and of dilution (River Severn observations) upon sewage, which the Royal Commissioners have already received from us, it was shown that the B. coli tended to die out both in the earth and sand composing the filters, and in the water and mud of the River Severn. It was explained, that once outside the alimentary tract the B. coli was not in the most suitable environment for its multiplication, and that the innumerable coarser bacteria of putrefaction, in their rapid multiplication, used up the food materials, and produced products which were in all probability injurious to the more sensitive B. coli. If in this struggle for existence the bacillus coli is outdistanced by coarser bacteria, and soon perishes, there is still more reason why the bacillus of typhoid should not long survive outside the alimentary tract. The reason for supposing this is that it has been shown that the B. typhi abdominalis is much more sensitive than the B. coli to certain reagents, and that even the slight acid reaction of the potato retards its growth, whilst the B. coli grows luxuriantly. Nevertheless, our work would not have been complete in this direction unless we had by exact methods determined longevity of the typhoid bacillus in sewage and sewage effluents.

In these experiments partially sterilised and non-sterilised sewage and effluents have been used in order to see whether these fluids exerted a greater typhocidal action in the presence or absence of putrefactive bacteria.

A further reason for undertaking the investigation was that owing to the bile salt agar method a simpler means exists for the isolation and identification of this organism in sewage when present amongst overwhelming numbers of the ordinary putrefactive bacteria.

Methods.—Bile Salt Agar was chosen as the medium, because though it has a somewhat inhibiting effect upon B. typhosus yet it has at a temperature of 42° C. very marked power of preventing the growth of the more common organisms of the soil and water. Thus though it would not give the exact number of B. typhosus present yet by cutting out other organisms it would allow the use of lower dilutions; and by the characteristic reaction of B. coli a distinction could be made which would lessen the number of subcultures necessary.

The composition of bile salt agar has been detailed elsewhere, but to save the trouble of reference it may as well be given here.

Sodium Taurocholate (Ox bile)	0·5%
Peptone	2·0%
Agar	1·5%
Lactose	1·0%
Water	q.s.

The lactose is not added till after filtration, as overheating causes changes which spoil the medium.

The incubation temperature was always 42° C.; and the duration of incubation 48 hours.

Organisms producing acid from lactose cause a cloudiness in the medium round them. It is thus easy in most cases to separate the acid-producers from the non-acid producers. Some organisms (*e.g.*, Bacillus Capsulatus of Pfeiffer), however, when on the surface seem to produce acid at first and later alkali. Consequently the haze does not always appear round the surface colonies; but the majority of these colonies are distinguishable by their greater opacity. Again some organisms produce only a slight amount of acid from lactose in 48 hours, and have no visible haze round their colonies, but these are few in number, and do not mar the results to any great extent. As the B. typh. does not give rise to acid in a lactose medium it is easy to separate it and other similar organisms from the large number of acid-producers.

The plates were poured and incubated for 48 hours. Then the total number of colonies on the plates was counted, and from this was deducted the number of colonies which were obviously not B. typh., and thus an estimate was formed of the number of colonies which might be B.t.a. Cultures were made from the colonies in this latter group, and the organisms worked through the usual media and the percentage of B.t.a. cultures ascertained. From this percentage was calculated the number of B.t.a. in the liquid under examination. It may be said that this is a very inaccurate method, and that it is impossible to judge of the deep colonies from the results of the cultivation of those on the surface. Quite true, but considering the very large number of B.t.a. put into the various liquids and their enormous preponderance over the other organisms present, any error due to this method is an error on the right side, that is, the B.t.a. are, if anything, over and not under estimated. For the purpose of these experiments a slight over-estimation is of no importance, and is to a certain extent corrected by the inhibition due to the medium. Consequently we think that the results may be taken as fairly representing the conditions obtaining at the time the experiments were made.

The fluids used were obtained from Leeds, and were crude sewage; effluent from the open sewage tank; effluent from No. 2 Dibbin bed, and effluent from the Cameron bed.

The experiments may be divided into four series, series 3 and 4 being merely a repetition of Series 1 and 2, except that Cameron effluent was used instead of Dibdin effluent.

Series 1 and 3.—These experiments were to ascertain the effect upon the B.t.a. of the metabolic products of the organisms already growing in the liquid. For this purpose, as complete sterilization would have had a detrimental effect, about 600 c.c. of each liquid were placed in a wool stoppered flask, and the flask heated to 65° C. for from half to three-quarters of an hour. It was hoped by this means to kill most of the organisms present without destroying their products. When cool the flasks were inoculated with B.t.a. (Bac. typhi. abdominalis.)

Series 2 and 4.—These were to find out the effect of the crude liquids (*i.e.*, organisms and their products) upon the B.t.a. About 600 c.c. of each liquid were placed in a wool-stoppered flask and inoculated with B. t.a.

Plates were made from all the flasks just before inoculation to find out the number of organisms present.

Plates were also made directly after inoculation, so that the number of B.t.a. inoculated might be known.

The flasks were kept in a dark cupboard at room temperature, and plates were poured on several later dates and the numbers of B.t.a. present ascertained.

The numbers are the average of three plates, except in Series 1, before inoculation, when only one plate was poured from each flask.

The following contractions are used to indicate the various liquids:—

C.S.a.—Crude sewage partially sterilized by heating to 65° C.

O.S.T.a.—Open sewage tank effluent sterilized by heating to 65° C.

Dibdin a.—Dibdin bed No. 2 effluent sterilized by heating to 65° C.

Cameron a.—Cameron bed effluent sterilized by heating to 65° C.

C.S. b.—Crude sewage.

O.S.T.b.—Open sewage tank effluent.

Dibdin b.—Dibdin bed No. 2 effluent.

Cameron b.—Cameron bed effluent.

A small "1" placed after the letters indicates "before inoculation with B.t.a."

The organisms used for inoculation were:—

Series 1 and 2.—A B.t.a. obtained from Král.

Series 3 and 4.—A B.t.a. isolated by myself from the fœces in a case of enteric fever.

Both organisms were bacilli, actively motile whenever examined; they did not stain by Gram, they produced only acid in litmus glucose broth, either no change or decolorisation in litmus lactose broth, general

turbidity in ordinary broth, and no change or slight acid in litmus milk. On agar and gelatine they gave the usual growth of the B.t.a. Indol was sometimes produced and sometimes not. Both gave the serum reaction. Active motility was considered essential, and if in the subcultures an organism was not distinctly motile it was put down as doubtfully so, and therefore not B. typhosus.

1 c.c. of a 24 hours broth culture was put into each flask. The broth tube was not well shaken, and consequently some flasks received a larger number of organisms than others.

In Series 1 the partial sterilisation was most effective, as no colonies appeared on the plates made *after heating*, but *before inoculation*. The sterilisation was not complete, however, as extraneous organisms later made their appearance in gradually increasing numbers, and the condition approximated to those in the unheated flasks.

At first, as the flasks had been apparently sterile, only a single sub-culture was made, as it was thought only B.t.a. was present, but later, when it was obvious that there were other organisms, several subcultures were made. On some occasions the dilutions were too high, and there were only a few colonies on the plates, so many cultures could not be made.

In series 3 it was found that many organisms had resisted the heat applied. In this series the flasks were placed in a water bath kept at 67° C. No thermometer was put into the liquid in the flask, as was done in the case of the first series.

In these series also the dilutions were found to be occasionally too high.

Consequently, one cannot draw any *definite* conclusion as to the effect of the metabolic products alone upon the growth of the B.t.a.

Conclusions.

I.—Partially Sterilised Crude Sewage, inoculated with B. typhi abdominalis.

(a) That the organisms which have not been killed by the partial sterilization multiply and continue to do so for at any rate 17 days.

(b) That amongst these bacteria there is one which gives many of the reactions of the B.t.a., and might be confounded with it.

(c) That the B. typhosus does not multiply in this liquid, but gradually dies out, and that the duration of its life is greatly influenced by the presence of other organisms—the greater the number of the latter the shorter the time the B.t.a. remains alive.

II.—Crude Sewage, inoculated with B.t.a.

(a) That the total number of organisms gradually decreases.

(b) B. typhosus. In the first experiment, typhoid bacilli corresponding to the bacilli inoculated were recovered after 13 days; and these bacilli appeared to decrease at much the same rate as the other organisms. In the second experiment (the first examination after inoculation being made at the end of 6 days), though some 8,000,000 of B.t.a. per c.c. were inoculated, this organism was never recovered, nor was any organism resembling B.t.a. isolated, even though such an organism was present before inoculation. Thus in this case the B. typhosus must have died out rapidly. It may be concluded then, that the B.t.a. does not multiply, but dies more or less rapidly in crude sewage.

III.—Open Sewage Tank Effluent, partially sterilized, inoculated with B.t.a.

(a) That the organisms which have resisted the sterilization increase for a time, but soon begin to decrease.

(b) That the organism resembling B.t.a., which was isolated from crude sewage, is also present in this effluent.

(c) B. typhosus. In the first experiment this organism was recovered after 15 days, but in the second not after 10 days. That this bacillus does not multiply in this medium, but gradually dies out, the decrease in numbers proceeding at a more rapid rate than in the case of the other organisms in the later stages of the experiment.

(d) That this medium is less favourable than partially sterilized crude sewage to the growth of aerobic organisms in general, but the B. typhosus appears to be able to survive longer in it.

IV.—Open Sewage Tank Effluent.—Untreated.

(a) That the total number of organisms gradually decreases, and the medium is distinctly unfavourable to their growth.

(b) That the B.t.a. decreases at a rapid rate, but still survives longer in this medium than in crude sewage, having been recovered at the end of fifteen and seventeen days.

V.—Dibdin No. 2 Bed Effluent partially sterilized.

(a) That the total number of organisms gradually decreases.

(b) That the bacillus typhosus is capable of surviving as long in this medium as in open sewage tank effluent, having been recovered at the end of fifteen days.

VI.—Dibdin No. 2 Effluent.—Untreated.

(a) That a gradual decrease in the number of all organisms takes place.

(b) That the B. typhosus survives as long, but not in such numbers as it does in the partially sterilized effluent from this bed.

VII.—Cameron Bed Effluent, partially sterilized.

That the B. typhosus appears to die out more quickly in this effluent than in any of the fluids used.

There were 8,000,000 B. typhosus per c.c. at the commencement of the experiment, and these had decreased to less than 3,000 per c.c. in six days, and to less than 30 per c.c. in four days longer.

All organisms appeared to decrease rapidly.

VIII.—Cameron Bed Effluent.—Untreated.

Here again the conditions appear unfavourable to the growth of organisms.

The number of B. typhosus at the beginning of the experiment were some 12,000,000 per c.c., and yet none were recovered at the end of six days or later.

The total number of bacteria per c.c. was at the end of six days only some 7,000, four days later some 800, and seven days later had fallen to some 200 per c.c.

Thus this effluent seems to be much more highly purified than the Dibdin effluent.

As a final conclusion it may be stated that the fluids experimented with are inimical to the growth of the Bacillus typhosus, and if these pathogenic bacilli find their way into a bacteriological system of treatment they meet with conditions hostile to their multiplication.

We know that typhoid bacilli must find their way into the sewage from the excreta of persons suffering from typhoid, but they cannot be in large numbers, and in the various samples of crude sewage which we have examined we have not found any. Therefore it may be concluded that allowing that these bacilli do reach biological beds or septic tanks, they are present in such small numbers, and the conditions are so adverse to their existence, that they will not survive the treatment. But if from any cause they arrived to the beds or tanks in such large numbers as the B. coli, then certainly they might appear in the effluent just as the B. coli does. But, as in the case of the latter bacillus, so also in the case of the B. typhosus, there is no tendency to multiplication in the effluent.

November 1901.

A. MacCONKEY.

REMARKS.

Series I.

C.S. (a) Partially Sterilized Crude Sewage.

As regards the total number of organisms there is an initial decrease and then a gradual increase.

As regards B. typh. there appears to be a large initial decrease, then a slight increase and then a decrease.

The heating obviously had not killed all the organisms present, but so few had escaped that their numbers may be neglected at first, and almost all the organisms present considered to be typhoid. This would give the initial number of B.t.a. as some 300,000 per c.c.

The countings of 3rd and 9th April cannot be taken into account as the dilution was too great, and there were too few colonies on the plates to allow an accurate estimate to be made. On the 11th April, *i.e.*, nine days after inoculation, the number of B.t.a. had decreased to 22,000 per c.c., while the extraneous organisms had increased to 51,000. On 15th April (13 days after inoculation), the B.t.a. numbered 6,300 per c.c., and the other organisms 71,400. On the 17th (15 days after inoculation), no B.t.a. were recovered.

Plates were also poured on 1st May (one month after inoculation). These plates had many colonies like B.c.c., and were crowded with very small opaque white colonies. There were a few colonies which somewhat resembled B.t.a. These latter were sub-cultured and found not to be B.t.a. Thus B. typh. was recovered from partially sterilized sewage 13 days after inoculation, but apparently it will not increase in such a medium.

At the end of one month the total numbers had fallen to some 3,000 B.c.c.-like organisms with others which were not B.t.a.

Remarks.

Series I.

O.S.T. (a). Partially Sterilised Open Sewage Tank Effluent.

Total number of Organisms :

Beginning of experiment - - - - - - - - 354,000 per c.c.
End of experiment (15 days later) - - - - - - 45,400 „
A gradual decrease took place throughout the duration of the experiment.
At the end of one month about - - - - - - - 47,000 „

Extraneous Organisms :

Did not make their appearance at first.

On the seventh day they had reached a total of some 130,000, and then they gradually decreased to some 34,000 on the 15th day of the experiment.

B.t.a. :

Initial number - - - - - - some 350,000 per c.c.
A gradual decrease to - - - - - „ 11,000 „ in 15 days.

Thus the B.t.a. have decreased at a more rapid rate than the other organisms. The latter after an initial increase soon decrease, and thus the medium appears to be less favourable to their growth than partially sterilized crude sewage in which they continued to increase.

B t.a. was not recovered from plates poured at the end of one month.

SERIES I.

DIBDIN, No. 2 Bed, Effluent, heated to 65° C. for half hour and inoculated with Bacillus Typhosus

D. (a).

—	2 April.	3 April.	9 April.	11 April.	15 April.	17 April.
1. Total number of organisms per c.c.	407,000 Dilution $\frac{1}{10,000}$ Average 40·7 per plate.	100,000 Dilution $\frac{1}{10,000}$ Average 10 per plate.	80,000 Dilution $\frac{1}{10,000}$ Average 8 per plate.	17,000 Dilution $\frac{1}{1,000}$ Average 17 per plate.	5,400 Dilution $\frac{1}{1,000}$ Average 5·4 per plate.	6,200 Dilution $\frac{1}{100}$ Average 62 per plate.
2. Number of organisms obviously not B. typhosus.	—	—	—	—	—	—
3. Number of organisms which might be B. typhosus.	407,000	100,000	80,000	17,000	5,400	6,200
4. Number of sub-cultures made from Group 3.	1 Died before it could be worked out.	1	2	2	4	2
5. Percentage of Group 4 which on cultivation gave the reactions of B. typhosus.		All reactions except motility.	100 per cent.	50 per cent.	100 per cent. gave all reactions except motility.	50 per cent.
6. Number of B. typhosus per c.c.			80,000	8,500		3,100

In this case only a small number of sub-cultures were done, because it was thought that only B.t.a. was present.

REMARKS.

Series I.

D. (a). Dibdin No. 2 Bed Effluent, partially sterilised.

Total Number of Organisms:

At beginning of experiment - - - - - - - -	407,000 per c.c.
At end of experiment (15 days) - - - - - - -	6,200 „
At end of one month - - - - - - - - - -	100 „

Extraneous Organisms:

The plates made before inoculation showed no growth, and throughout the experiment no obviously non-typhoid colonies appeared on the plates.

Sub-cultures, however, showed the presence of bacteria other than B.t.a., and the majority of these organisms differed from B.t.a. only in the amount of their motility. There was at first an increase and then a continued gradual decrease in their numbers.

B.t.a.:

Number at beginning of experiment - - - - -	some	400,000 per c.c.
Number at end - - - - - - - - - - -	„	3,000 „

The decrease is continued from the commencement of the experiment, and is more marked than in the case of similar Crude Sewage or Open Sewage Tank Effluent. This medium would therefore appear to be less favourable to the growth of B.t.a. than either similar Crude Sewage or Open Sewage Tank Effluent.

SERIES II.

CRUDE SEWAGE, inoculated with Bacillus Typhi Abdominalis.

C.S. (b).

—	2 April.	3 April.	9 April.	11 April.	15 April.	17 April.
1. Total number of organisms per c.c.	1,184,000 Dilution $\frac{1}{10,000}$ Average 118·4 per plate.	250,000 Dilution $\frac{1}{10,000}$ Average 25 per plate.	27,000 Dilution $\frac{1}{10,000}$ Average 2·7 per plate.	10,000 Dilution $\frac{1}{1,000}$ Average 10 per plate.	6,000 Dilution $\frac{1}{1,000}$ Average 6 per plate.	4,000 Dilution $\frac{1}{100}$ Average 40·4 per plate.
2. Number of organisms obviously not B. typhosus.	160,000	114,000	4,000	3,700	1,000	1,670
3. Number of organisms which might be B. typhosus.	1,024,000	136,000	23,000	6,300	5,000	2,370
4. Number of sub-cultures made from Group 3.	22 17 died before they could be worked out.	8	2	3 1 died before it could be worked out.	5	2
5. Percentage of Group 4 which on cultivation gave the reactions of B. typhosus.	20 per cent.	50 per cent.	All reactions, of B.t.a. except motility.	50 per cent.	20 per cent.	All reactions, except mo tility.
6. Number of B. typhosus per c.c.	205,000	68,000		1,850	1,000	

REMARKS.

Series II.

C.S. (b). Untreated Crude Sewage.

Total Number of Organisms :

There is a gradual decrease in number throughout the 15 days duration of the experiment from one million down to a few thousands.

Extraneous Organisms :

A gradual decrease from some 900,000 down to 5,000 per c.c.

B.t.a. :

A gradual decrease from some 200,000 down to 1,000 per c.c.

Thus the B.t.a. have decreased at about the same rate as the other organisms, and it cannot be said that Crude Sewage has any marked effect upon the growth of B.t.a., except that this organism has not shown any increase in this medium.

Plates were also poured on May 1st. (1 month after inoculation.) The total number of organisms was about 2,000 per c.c. No B.t.a. were recovered.

SERIES II.

Open Sewage Tank Effluent inoculated with Bacillus Typhosus.

O.S.T. (b).

	2 April.	3 April.	9 April.	11 April.	15 April.	17 April.
1. Total number of organisms per c.c.	117,000 Dilution $\frac{1}{10,000}$ Average 11·7 per plate.	234,000 Dilution $\frac{1}{10,000}$ Average 23·4 per plate.	60,000 Dilution $\frac{1}{10,000}$ Average 6 per plate.	22,400 Dilution $\frac{1}{1,000}$ Average 22·4 per plate.	2,700 Dilution $\frac{1}{1,000}$ Average 2·7 per plate.	2,400 Dilution $\frac{1}{100}$ Average 23·7 per plate.
2. Number of organisms obviously not B. typhosus.	—	14,000	4,000	2,000	1,000	400
3. Number of organisms which might be B. typhosus.	117,000	220,000	56,000	20,000	1,700	2,000
4. Number of sub-cultures made from Group 3.	5 2 died before they could be worked out.	9	2	9	7	2
5. Percentage of Group 4 which on cultivation gave the reactions of B. typhosus.	66 per cent. gave all reactions except motility.	66 per cent.	50 per cent.	56 per cent.	100 per cent. gave all reactions except motility.	50 per cent.
6. Number of B. typhosus per c.c.	—	146,000	23,000	11,400	—	1,000

Remarks.

Series II.

O.S.T. (b). Open Sewage Tank Effluent.

Total number of organisms:

Initial number	some	117,000 per c.c.
After 24 hours	„	234,000 „
After 7 days	„	60,000 „
After 15 days	„	2,400 „
After 1 month	„	200 „

Extraneous organisms:

At the end of 24 hours they had reached a total of 88,000 per c.c. There was apparently no further increas but a gradual decrease to some 1,400 per c.c. in 15 days.

B.t.a.:

The initial number was doubtful. A large number of B.t.a. was inoculated, and yet on cultivation none of the organisms isolated from the plates gave all the reactions of the B. typhosus. The motility was not sufficiently marked. At the end of 24 hours the B.t.a. numbered 146,000 per c.c., and then a decrease took place until at the end of 15 days there were only 1,000 per c.c. Thus they decreased at about the same rate as the other bacteria, and it cannot be said that the presence of the other organisms had any marked effect upon the growth of B.t.a.

The B. typhosus seems to live in open sewage tank effluent much as it does in crude sewage.

SERIES II.

D. (b).

Dibdin, No 2 Bed, Effluent inoculated with Bacillus Typhosus.

——	2 April.	3 April.	9 April.	11 April.	15 April.	17 April.
1. Total number of organisms per c.c.	204,000 Dilution $\frac{1}{10,000}$ Average 20·4 per plate.	420,000 Dilution $\frac{1}{10,000}$ Average 42 per plate.	3,000 Dilution $\frac{1}{10,000}$ All the 3 plates sterile.	770 Dilution $\frac{1}{100}$ Average 7·7 per plate.	346 Dilution $\frac{1}{100}$ Average 3·4 per plate.	214 Dilution $\frac{1}{10}$ Average 31·4 per plate.
2. Number of organisms obviously not B. typhosus.	—	—	—	100	70	64
3. Number of organisms which might be B. typhosus.	204,000	420,000	3,000	670	270	150
4. Number of sub-cultures made from Group 3.	5 3 died before they could be worked out.	10	None.	4	3	2
5. Percentage of Group 4 which on cultivation gave tbe reactions of B. typhosus.	50 per cent.	70 per cent.	—	25 per cent.	66 per cent. gave all reactions of B.t.a. except motility.	50 per cent.
6. Number of B. typhosus per c.c.	102,000	294,000	—	170	—	75

Remarks.

Series II.

D. (b). Untreated Effluent from Dibdin, No. 2. Bed.

Total number of organisms :

At beginning of experiment - - - - - - -	204,000	per c.c.
At end of 24 hours - - - - - - - - -	420,000	„
At end of 15 days - - - - - - - - -	214	„
At end of 1 month - - - - - - - - -	20	„

Extraneous organisms :

Initial number - - - - - - - - -	some	102,000	per c.c.
After 24 hours - - - - - - - - -	„	126,000	„
After nine days - - - - - - - - -	„	600	„
After 15 days - - - - - - - - -	„	130	„
After 1 month - - - - - - - - -	„	20	„

B.t.a. :

At beginning of experiment - - - - - - -	102,000	per c.c.
At end of 24 hours - - - - - - - -	294,000	„
At end of 9 days - - - - - - - - - -	170	„
At end of 15 days - - - - - - - - -	75	„

The diminution in the number both of B.t.a. and other organisms is much more marked than in any of the other liquids used in this series, and it appears that even merely partial sterilisation renders this medium more favourable to the longevity of B.t.a.

SERIES III.

CRUDE SEWAGE heated for half to three-quarter hours at about 65° C.

C.S. (a).

—	8 May.	14 May.	18 May.	25 May.
1. Number of organisms before inoculation per c.c.	50 B.c.c.-like - - - 11 B.t.a.-like numerous minute white colonies.	Plated un-diluted.		
2. Number after inoculation per c.c.	3,200,000 Dilution $\frac{1}{10,000}$ Average 320 per plate.	640,000 Dilution $\frac{1}{10,000}$ Average 64 per plate.	1,534,000 Dilution $\frac{1}{10,000}$ Average 153·4 per plate.	1,617,000 Dilution $\frac{1}{10,000}$ Average 161·7 per plate.
3. Number which were obviously not B. typhosus.	—	434,000	344,000	204,000
4. Number which might be B. typhosus.	Some 3,000,000	206,000	1,190,000	1,413,000
5. Number of cultures made from Group 6.	3	6	8	6
6. Percentage of cultures (5) which correspond to B. typhosus.	100 per cent.	66 per cent.		
7. Number of B. typhosus per c.c.	About 3,000,000	About 131,000		

REMARKS.

Series III.

C.S. (a). Partially sterilized Crude Sewage.

Total Number of Organisms per c.c.:

At beginning of experiment	3,200,000	per c.c.
After 6 days	640,000	„
„ 10 „	1,534,000	„
„ 17 „	1,617,000	„

No. of Extraneous organisms:

At beginning of experiment	about	200	„
After 6 days		509,000	„
„ 10 „	apparently	1,500,000	„
„ 17 „	„	1,600,000	„

B.t.a.:

At beginning of experiment	some	3,000,000	„
After 6 days	„	130,000	„
„ 10 „	not recovered.		
„ 17 „	„	„	

This experiment confirms the similar one in Series I. The B.t.a. gradually decrease (in this case much more quickly than before), while the other organisms continue to increase.

It will be seen by referring to the table of Cultures made on May 8th (the first day of experiment) that there was present in the sewage an organism very like B.t.a. except in its motility.

SERIES III.

OPEN SEWAGE TANK EFFLUENT heated half to three-quarter hours at 65° C.

O.S.T. (a).

—	8 May.	14 May.	18 May.	25 May.
Number of organisms before inoculation.	3 B.c.c.-like. Plated undiluted.	—	—	—
Number after inoculation -	1,734,000 Dilution $\frac{1}{10,000}$ 173·4 per plate.	474,000 Dilution $\frac{1}{10,000}$ 47·4 per plate.	1,220,000 Dilution $\frac{1}{10,000}$ 122 per plate.	274,000 Dilution $\frac{1}{10,000}$ 27·4 per plate.
Number which were obviously not B. typhosus.	—	—	7,000	—
Number which might be B. typhosus.	1,734,000	474,000	1,213,000	274,000
Number of cultures made from Group 4.	3	6 All the surface colonies on one plate.	5	6
Percentage of cultures (5) which correspond to B. typhosus.	100 per cent.	100 per cent.	20 per cent.	—
Number of B. typhosus per c.c.	About 1,700,000	About 470,000	About 240,000	—

REMARKS.

Series III.

O.S.T. (a). Partially sterilized Open Sewage Tank Effluent.

otal number per c.c. :

At beginning of experiment	-	1,700,000 per c.c.
After 6 days	-	474,000 „ „
„ 10 „	-	1,220,000 „ „
„ 17 „	-	1,274,000 „ „

xtraneous organisms :

At beginning of experiment	-	3 per c.c
After 10 days	-	980,000 „ „
„ 17 „	-	270,000 „ „

The few organisms, other than B.t.a., which were present at the commencement of the experiment increased to
out 1 million per c.c., and then began to decrease.

t.a. :

At beginning of experiment	-	1,700,000 per c.c.
After 6 days	-	470,000 „ „
„ 10 „	-	240.000 „ „
„ 17 „	-	not recovered

Thus the B. typhosus does not increase but steadily decreases in this medium.

SERIES III.

CAMERON BED EFFLUENT heated from half to three-quarters of an hour.

Cameron (a).

——	8 May.	14 May.	18 May.	25 May.
1. Number of organisms before inoculation.	Apparently sterile. Plated undiluted.	—	—	—
2. Number after inoculation -	8,800,000 Dilution $\frac{1}{10,000}$ 880 per plate.	Dilution $\frac{1}{10,000}$ too great, no growth on plates.	Dilution $\frac{1}{100}$ too great, no growth on plates.	Undiluted. No growth on plates.
3. Number which were obviously not B. typhosus.	—	—	—	—
4. Number which might be B. typhosus.	8,800,000	—	—	—
5. Number of cultures made from Group 4.	3	—	—	—
6. Percentage of cultures (5) which correspond to B. typhosus.	100 per cent.	—	—	—
7. Number of B. typhosus per c.c.	About 8,500,000	Less than 3,300	Less than 33	—

REMARKS.

Series III.

Cameron (a). Partially Sterilized Cameron Bed Effluent.

Total number of organisms:

At beginning of experiment - - - - - - - 8,800,000 per c.c.

These were apparently almost all B.t.a.

The decrease in numbers in this medium is most marked.

No extraneous organisms made their appearance, which is in marked contrast to the other liquids of this series.

SERIES IV.

CRUDE SEWAGE, Untreated.

C.D. (b).

—	8 May,	14 May.	8 May.	25 May.
. Number of organisms before inoculation.	170,000 127,000 B.cc.-like. 43,000 B.t.a.-like. Plated $\frac{1}{10,000}$ 17 per plate.	—	—	—
2. Number after inoculation -	9,280,000 Dilution $\frac{1}{10,000}$ 928 per plate.	274,000 Dilution $\frac{1}{10,000}$ 27·4 per plate.	94,000 Dilution $\frac{1}{10,000}$ 9·4 per plate.	34,700 Dilution $\frac{1}{1,000}$ 34·7 per plate.
3. Number which were obviously not B. typhosus.	330,000	180,000	57,000	12,000
. Number which might be B. typhosus.	8,950,000	94,000	37,000	22,700
5. Number of cultures made from Group 4.	5	6	5	4
6. Percentage of cultures (5) which correspond to B. typhosus.	100 per cent.	—	—	—
7. Number of B. typhosus per c.c.	about 8,500,000	—	—	—

REMARKS.

Series IV. C.S. (b). Untreated Crude Sewage.

Total number of organisms :

At beginning of experiment - - - - - -		9,000,000 per c.c.
After 6 days - - - - - - - - - -		274,000 „
„ 10 „ - - - - - - - - - -		94,000 „
„ 17 „ - - - - - - - - - -		34,000 „

Extraneous organisms :

At beginning of experiment - - - - - -		170,000 per c.c.
After 6 days - - - - - - -	apparently	270,000 „
„ 10 „ - - - - - - -	„	94,000 „
„ 17 „ - - - - - - -	„	34,000 „

B.t.a. :

At commencement of experiment - - - - - - 8,500,000 per c.c.
Not recovered on 6th day or later.

It must be concluded then that this sample of Crude Sewage was not favourable to the growth of B.t.a.

Here again [as in C.S. (a)] an organism which resembled B.t.a. was recovered from the Sewage before inoculation.

SERIES IV.

OPEN SEWAGE TANK EFFLUENT, Untreated.

O.S.T. (b).

——	8 May.	14 May.	18 May.	25 May.
1. Number of organisms before inoculation.	24,000 20,000 B.c.c.-like. 4,000 B.t.a.-like. Plated $\frac{1}{10,000}$			
2. Number after inoculation -	24,000,000 Dilution $\frac{1}{10,000}$ about 2,400 per plate.	34,000 Dilution $\frac{1}{10,000}$ 3·4 per plate.	5,400 Dilution $\frac{1}{1,000}$ 5·4 per plate.	2,870 Dilution $\frac{1}{100}$ 28·7 per plate.
3. Number which were obviously not B. typhosus.	14,000	—	3,000	270
4. Number which might be B. typhosus.	23,086,000	34,000	2,400	2,600
5. Number of cultures made from Group 4.	5	5 All from the same plate.	4	4
6. Percentage of cultures (5) which correspond to B. typhosus.	100 per cent.	100 per cent.	100 per cent.	25 per cent.
7. Number of B. typhosus per c.c.	About 23,000,000	About 30,000	About 2,000	About 600

REMARKS.

Series IV. O.S.T. (b). Untreated Open Sewage Tank Effluent.

Total number of organisms :

At beginning of experiment	- - - - - - - -	24,000,000 per c.c.
After 6 days	- - - - - - - - - - -	34,000 ,,
,, 10 ,,	- - - - - - - - - - -	5,400 ,,
,, 17 ,,	- - - - - - - - - - -	2,800 ,,

Extraneous organisms :

At beginning of experiment	- - - -	24,000 per c.c.
After 6 days	- - - - - - - -	?
,, 10 ,,	- - - - - - - - - - -	3,000 ,,
,, 17 ,,	- - - - - - - - - - -	2,000 ,,

B.t.a. :

At beginning of experiment	- - - -	23,000,000 per c.c.
After 6 days	- - - - - - - - - - -	30,000 ,,
,, 10 ,,	- - - - - - - - - - -	2,000 ,,
,, 17 ,,	- - - - - - - - - - -	600 ,,

There is a general decrease in total numbers of organisms, but more especially in the case of B.t.a.

From this liquid before inoculation there was obtained a Bacillus resembling B.t.a. in most particulars. It was not present in great numbers, at most 2,000 per c.c., and therefore it could not affect the initial number of B.t.a. If it has been included in the later numbers, it only makes the decrease in the number of B. typhosus more marked.

SERIES IV.

Cameron (b).

CAMERON BED EFFLUENT Untreated.

	8 May.	14 May.	18 May.	25 May.
1. Total number of organisms before inoculation.	About 6,000. B.t.a.-like. Plated 1/10,000			
2. Total number of organisms after inoculation.	16,000,000 Dilution 1/10,000 About 1,600 per plate.	6,700 Dilution 1/10,000 Too great, only two colonies on three plates.	840 Dilution 1/100 8·4 per plate.	189 Undiluted. 189 per plate.
3. Number of organisms obviously not B. typhosus.	—	3,400	670	101
4. Number of organisms which might be B. typhosus.	16,000,000	3,300	170	88
5. Number of cultures made from Group 4.	5	1	5	7
6. Percentage of cultures (5) which correspond to B. typhosus.	80 per cent.	—	—	—
7. Number of B. typhosus per c.c.	About 12,000,000.	—	—	—

REMARKS.

Series IV.

Cameron (b). Untreated Cameron Bed Effluent.

Total number of organisms :

At beginning of experiment	16,000,000	per c.c.
After 6 days	6,700	„
„ 10 „	840	„
„ 17 „	189	„

Extraneous organisms :

At commencement of experiment	4,000	per c.c.
After 6 days - apparently	6,700	„

and later, same as total number.

B.t.a. :

At commencement of experiment - - - - - - 12,000.000 per c.c.

No B.t.a. were recovered subsequently.

The decrease in all organisms is marked, but especially in the case of B.t.a.

FILTRATION EXPERIMENTS.

THE REDUCTION IN THE NUMBER OF BACTERIA IN A BIOLOGICAL EFFLUENT (DOUBLE CONTACT) BY MEANS OF FILTRATION.

BY PROFESSOR BOYCE AND DRS. MACCONKEY, GRÜNBAUM AND HILL.

Reasons for Making the Experiments.

The numerous analyses of biological effluents which were carried out by the Royal Commission having demonstrated that the total number of bacteria present in these effluents as well as the number of the *Bacillus coli communis* was usually large, the Commission decided that the effect of subsequent filtration of the effluent should be tried in order to see what further reduction could be effected. The most convincing way to have carried out this experiment would have been to filter the effluent on a large scale through some four feet of suitable soil, and over a considerable area. Owing to the difficulty of levels at West Derby this extensive experiment could not be conducted, and it was decided to make use of small experimental filters. Such small filters have in the past proved of considerable use in those engaged in sewage and water experiments, and under special circumstances, viz., when experimenting with pathogenic organisms, they obviate that risk of spreading infection which might occur in the case of experiments conducted on a large scale on a farm.

Nature of the Experiments.

The experiments consisted in passing at a definite rate a biological effluent of known bacterial impurity through four feet of sand or good soil, and in daily analysing the filtrate and in noting the reduction both in the total numbers of bacteria and in the *B. coli. communis* and the *B. enteritidis sporogenes*. The experiments were subsequently extended to ascertain whether if certain colour bacteria, viz., the *Bacillus prodigiosus* and the *B. pyocyaneus*, were placed in the biological effluent supplying the filters, they would appear in the filtrate, and if so how soon after filtration this would occur, also when they would disappear again. In the same way experiments were made with the Bacillus typhosus.

These experiments would show whether, if an effluent containing pathogenic organisms passed on to land, multiplication of these harmful organisms might or might not be expected to take place in the soil.

The filters were made in 9in. drain pipes, and were 4ft. deep, with the draw-off tap as close to the bottom as possible. Filters, 1, 2, and 4 were filled with sand; Filter 3 with light soil taken from one of the fields on the West Derby Sewage Farm. The bottom of each filter was filled with 3in. of graded gravel.

Filter 1 was washed by a continuous stream of tap water for 24 hours and subsequently with distilled water. In Filter 4 the sand was thoroughly washed before packing. Filters 2 and 3 were not washed.

The filters were started on November 8th by running on to them Dibdin Effluent obtained from the beds at the West Derby Farm.

The rate of flow was carefully adjusted. In the commencement it was at the rate of 4 litres per hour, which gives 1,900,000 gallons per acre per 24 hours; later the rate was reduced to 10 and 4 litres per 12 hours, or 392,000 and 157,000 gallons respectively per acre per 24 hours. At these rates the effluent dripped on to the filters, and the filtrate came away at about the same rate.

In calculating the rate of flow, we had the experience of the Water Engineer of the City of Liverpool.

After carefully collecting the filtrate from each filter, the following series of experiments were undertaken:—

1. The original effluent flowing on to all four filters was carefully analysed.
   - (a.) For numbers.
   - (b.) For B. coli communis.
   - (c.) For B. enteritidis sporogenes.
   - (d.) For other organisms.

2. The filtrate from each filter was examined precisely as in the preceding case.

The Bacteriological Analyses. Methods.

For quantitative analysis six gelatine plates were made of each filtrate and incubated for 3 days at 20° C.

For the analysis of B. coli communis, 1 in 1,000 carbolic agar was used and incubated at 42° C.

For the analysis of B. enteritidis sporogenes, freshly prepared milk tubes, heated to 80° C. for 15 minutes and incubated anaerobically, were used. For the test of pathogenicity guinea pigs have been used.

Results. Duration of Experiments.

The experiments extended from the 8th November, 1899, to April 6th, 1900.

Bacterial Condition of the Dibdin Effluent Employed.

The Dibdin effluent which supplied the filters was not, as the bacteriological analyses show, a good one.

The total number of bacteria per c.c. as the average of 26 analyses was 837,842.

The average number of B. coli communis out of 25 determinations was 9,812 per c.c.

The B. enteritidis sporogenes was present 7 times in 0·01 c.c. and 16 times in 0·1 c.c. out of 25 determinations.

In large quantity the effluent was turbid and occasionally underwent decomposition on standing.

The Action of the Filters.

The following is the summary of the four filters:—

Experimental Filter No. 1.

Number of determinations - - -	23
Average number of bacteria - -	79,780
Average number of B. coli - -	125

B. enteritidis sporogenes present twice.

Experimental Filter No. 2.

Number of determinations - -	24
Average number of bacteria - -	50,762
Average number of B. coli - -	590

B. enteritidis sporogenes present 8 times in 25.

Experimental Filter No. 3.

Number of determinations - - -	21
Average number of bacteria - -	31,665
Average number of B. coli communis -	49

B. enteritidis sporogenes present 11 times in 24.

Experimental Filter No. 4.

Number of determinations - - -	27
Average number of bacteria - -	113,790
Average number of B. coli communis -	432

B. enteritidis sporogenes present 5 times in 20.

In Table I. the total number of bacteria, the B. coli communis and the B. enteritidis sporogenes, are given in columns side by side. In Tables II. and III. the number of B. coli communis per c.c. is recorded in graphic form.

It was found difficult to regulate precisely the rate of flow over 24 hours, as accidents, due to blocking of pipes and variation of pressure, occurred, but from the number of observations made, it may be fairly concluded that marked diminution of the number of bacteria occurred when the rate of flow was decreased.

Tables II. and III. show very clearly the diminution in the numbers of the B. coli communis, the shaded columns showing at a glance the variations from day to day. Corresponding variations occurred with certain exceptions in the case of the total numbers of bacteria.

The rate of flow to commence with was 4 litres per hour. At this rate there is a slight average reduction both of the total numbers of bacteria and of the B. coli communis; this continued from Nov. 11th to Nov. 14th. On Nov. 15th the rate of flow was decreased to 10 litres in 12 hours. There is a marked diminution in numbers and B. coli except in the fourth filter, where the rate of flow was irregular. On the 16th and 17th November the rate of flow was still further decreased to 4 litres in 12 hours, and there is a corresponding diminution in the number of bacteria. This rate was fairly evenly maintained in Filter No. 3 to the end of the observation on January 10th, and the B. coli in the filtrate remained very low. On Dec. 1st the rate of flow in Filters

Nos. 1, 2, and 4 was increased to the original speed of 4 litres per hours, and there is a corresponding rise of B. coli until Dec. 5th, when the rate was again reduced to 4 litres per 12 hours. At the slow rate of flow of 4 litres in 12 hours there is a very great diminution in the B. coli communis, the number in some observations falling below 10 per c.c., whereas the effluent which went on contained in round numbers 10,000 B. coli per c.c.

Influence of the Composition of the Filter upon the Quality of the Filtrate.

On looking at Tables I.-III. it will be seen that the filter composed of the fine sandy soil gave the greatest reduction in the number of the B. coli communis.

Filters 1, 2 and 3 contained to commence with all kinds of bacteria, those of the earth filter, No. 3 being naturally especially numerous, as it was light mould taken from one of the fields of the sewage farm. The sand of filter 4 on the other hand, had been very carefully washed, and therefore contained fewer organisms. But, as seen by the Tables, the results of this clean sand filter are as regards the B. coli communis less satisfactory than the earth filter. It is most probable that the multitude of other organisms which are present in the mould act injuriously upon the B. coli and lessens its chances of passing through in the filtrate. Earth also, by forming a more compact mass than sand, will no doubt act as a more efficient filter.

In none of the experiments is there evidence of the multiplication of the B. coli in the substance of the filter; if there had been, one would have expected an increase in the filtrates towards the conclusion of the experiments. This did not occur.

In conclusion the experiments indicate that the reduction in numbers of the bacteria and of the B. coli is both due to filtration, being dependent therefore upon the rate of flow and the depth and nature of filter, and also to biological action, which further produces a reduction in intestinal organisms like the B. coli. In the struggle for life in the filter the conditions are more favourable to the survival and growth of the organisms which abound in earth than to the B. coli group, which are normally parasitic in the intestine, and the products of the former will act injuriously upon the life of the B. coli communis.

EXPERIMENTS WITH THE FILTRATION OF SPECIAL BACTERIA, VIZ., BACILLUS PRODIGIOSUS, B. PYOCYANEUS, B. TYPHOSUS.

Duration of Experiments.

The experiments were made from January 12th, 1900, to April 6th, 1900.

Method.

To the effluent which supplied the four filters was added the scrapings from the surfaces of Agar plates upon which were growing cultivations of the B. prodigiosus and B. pyocyaneus.

Reasons for Using B. Prodigiosus and B. Pyocyaneus.

These organisms were used because owing to their brilliant colours they could readily be recognised if present in plate cultivations of the filtrates.

Rate of Flow of Filters.

The rate of flow varied from 10 to 4 litres per 12 hours, and the filtering action as regards the total number of all kinds of bacteria present is graphically recorded in Tables IV. and V. by black columns, whilst the smaller red and green columns indicate the presence of B. prodigiosus or B. pyocyaneus.

Results.

The first inoculation of the effluent supplying filters with B. prodigiosus and B. pyocyaneus took place on January 12th. On the 13th and 15th no coloured organisms had appeared, and the effluent was again plentifully inoculated with B. prodigiosus. No B. prodigiosus appeared in the filtrate, and a fresh inoculation was made. Bacteriological analyses were made daily, but it was not till January 23rd, or ten days after the first inoculation. that the B. prodigiosus appeared in the filtrate of filters No. 1 and No. 2, and then they were present in the proportion on an average of only 33 per c.c.; the total number of bacteria present at the same time varied from 500 to 1,500 per c.c.

The next date on which B. prodigiosus appeared was on January 30th; it was only present in the filtrate of filter No. 1 to the extent of 34 per c.c. Upon no subsequent occasion to the conclusion of the observations upon April 6th was the B. prodigiosus found.

Up to January 30th the B. pyocyaneus had not appeared upon the plates. On February 1st a green organism was round in the plates made from the filtrate of filter No. 4, and again on February 12th a similar organism appeared in the filtrate from filter No. 3. The green colour producing bacteria were present in very small proportion. It thus took seventeen days from the original inoculation before the B. pyocyaneus appeared in the filtrate in very small quantity in two out of the four filters.

On March 5th and 12th the surfaces of filters 2 and 3 were carefully examined for the B. prodigiosus and the B. pyocyaneus, but neither organism was found.

Results.

These experiments with the two coloured bacteria corroborate the previous observations upon the B. coli. Although large quantities of these organisms were run on to the filters, they only appeared in the filtrates of some of the filters after many days, and then only in very small numbers. They had been intercepted by the filtering action of the material of the filters. And as in the case of the B. coli, there was no evidence of multiplication in the filters. Had this taken place, these organisms would have been regularly found in the filtrates. On the contrary, again, as in the case of the B. coli, the conditions were not favourable to their multiplication. This is shown by the fact that analysis of the sand of the filters on March 5th failed to show them, they had died out.

Experiments with Bacillus Typhosus.

It having been shown in the previous experiments that both the conditions for the growth and multiplication of the B. coli, B. prodigiosus, and B. pyocyaneus in the filters were not favourable, and also that by the action of filtration these organisms were greatly reduced in their passage through the filters, it was considered useful to ascertain whether the B. typhosus, the bacterium which more than any other renders sewage nocuous, behaved like those organisms, or whether there was evidence that they multiplied in the filters if they were supplied to them in the effluent which was poured on them.

In experiments with the B. typhosus there is very great difficulty in recognising colonies of this bacillus in plate cultivations of the filtrate owing to the presence of the B. coli. This renders it necessary to pick out all the coli-like colonies and to subject them to special differential tests in order to ascertain whether some of them may not be typhoid colonies. When these experiments were made MacConkey's medium had not been introduced, and all the analyses were made with Carbol Agar, in which medium the colon and typhoid colonies closely resemble one another.

The experiments were commenced on February 14th, when 13 litres of effluent which was allowed to run on to filter No. 3 (earth filter) at the rate of between 4 litres and 10 litres per 12 hours, was inoculated with 100 c.c. of a pure cultivation in broth of the typhoid bacillus.

The filtrate was tested on the 15th, 16th, 17th, and 19th, but no B. typhosus was found.

On the 19th, 200 c.c. of a typhoid culture were added to another 13 litres of effluent, and analyses of the filtrate made on the 22nd February and on the 5th of March, but without result.

On March 5th a fresh inoculation with 100 c.c. of typhoid culture took place, and this effluent was continuously poured through the filter till April 6th.

Bacteriological analyses of the filtrate were made on the 7th, 8th, 9th, 10th, 12th, 13th, 16th, 17th, 19th, 20th, 21st, 22nd, 23rd, 24th, 26th, and 29th March, and on the 4th and 6th of April, but the typhoid bacillus was never found.

Conclusions.

From February 14th to March 5th altogether 400 c.c. of a pure cultivation of the typhoid bacillus in broth mixed with the West Derby effluent had been passed into the earth filter, yet in no instance up to April 6th had any of the numerous colonies which had been picked out of the carbol agar plates given the reactions of the typhoid bacillus.

These results are more striking than those obtained in the case of the two coloured organisms, and demonstrate the action of the earth filter in removing a pathogenic organism like the B. typhosus from sewage. It is most probable that the action of the filter was similar to that described in the previous cases, viz., mechanical filtration, and the fact of the conditions in the filter being hostile to the growth and multiplication of the typhoid bacillus.

EXPERIMENTS WITH THE BACILLUS ANTHRACIS.

Experiments were commenced on March 7, 1900, when the effluent running on to filter No. 1 was inoculated with a culture of B. anthracis. The filtrate was tested by cultivation upon agar plates, incubated at 42° C., upon March, 8th, 9th, 10th, 13th, 16th, 19th, 20th, 21st, 22nd, 23rd, and 26th. On March 27th, the effluent was re-inoculated with a fresh broth culture of B. anthracis, and carbol agar exclusively used for the plate cultivations of the filtrate. Analyses upon March 28th, 29th, and April 4th, 5th, and 6th, all gave negative results. These experiments agree with the preceding ones. The rate of filtration varied between 10 and 4 litres per 12 hours.

General Conclusions.

When an effluent containing upon an average 800,000 bacteria per c.c. and 10,000 B. coli per c.c. is passed through a depth of 4 feet of soil at a slow rate (viz., between 10 and 4 litres per 12 hours), there is a very great reduction in the total numbers and in the B. coli, and the chance of a very pathogenic bacterium like the B. typhosus appearing in the filtrate must be exceedingly small.

When it is remembered that normally the B. typhosus is not present in the excreta of all cases of typhoid, whilst the B. coli is always present in the fæces, and that the proportion of typhoid cases to the total number of the population is not large, that typhoid excreta are usually disinfected, and that it has not been shown that favourable conditions exist in sewage for the multiplication of the typhoid bacillus, it appears evident that land or other method of efficient filtration must totally remove this organism from a Dibdin effluent did it happen to be present.

In the preceding experiments the B. typhosus was mixed with the effluent flowing on to the filters in far larger proportion than would ever occur in nature, and yet it could not be found in the filtrate.

November 1901. *R. Boyce.*

INVESTIGATION OF THE RIVER SEVERN IN THE SHREWSBURY DISTRICT.

By Professor Boyce and Doctors Grünbaum, MacConkey, and Hill.

CONTENTS

REASONS FOR THE INVESTIGATIONS.

The bacteriological analyses of the officers of the Royal Commission having shown that the effluents derived from bacterial methods of sewage treatment usually showed insufficient purification as measured by the "Coli" and "Enteritidis Sporogenes" tests; and as it was evident that these effluents might in the future pass into streams and rivers used for drinking or domestic purposes where the presence of pathogenic bacteria would be dangerous, it was considered of primary importance to ascertain the risk of allowing such effluents to pass into streams and rivers.

Although much had been published upon the effect of sewage pollution upon rivers, more especially upon the Continent, nevertheless definite bacteriological data based upon the most recent methods of measuring intestinal polution were wanting, and it was thought that with the improved methods, which the officers of the Commission had devised, much definite and practical information could be gained upon the following amongst other questions:—

1. WHAT HAPPENED TO THE INTESTINAL BACTERIA WHEN THEY PASSED INTO THE RIVER?

2. HOW FAR DOWN THE RIVER WERE THEY CARRIED? WAS THERE EVIDENCE OF MULTIPLICATION?

3. DID THEY ACCUMULATE AND MULTIPLY IN THE MUD OF THE RIVER?

4. AT WHAT DISTANCE BELOW THE SOURCE OF POLLUTION WAS IT SAFE TO DRINK THE WATER?

5. WHAT WAS THE SIMPLEST AND MOST RAPID MEANS OF DETECTING INTESTINAL BACTERIAL POLLUTION IN THE RIVER?

6. WHAT, IF ANY, WAS THE EFFECT OF SEASONS UPON THE BACTERIA OF THE RIVER?

It was originally intended to examine a river into which a biological effluent passed, but as a suitable place presenting this condition could not be found, it was determined to carry out the investigation upon the River Severn at Shrewsbury and to make the observations extend over a period of at least twelve months.

The River Severn at Shrewsbury presented great advantages for this investigation.

1. IT WAS COMPARATIVELY NEAR THE CENTRAL LABORATORIES AT LIVERPOOL.

2. IT WAS A TYPICAL EXAMPLE OF A RIVER USED FOR DRINKING AND DOMESTIC PURPOSES AND FOR FISHING.

3. ITS VOLUME AND VELOCITY COULD BE READILY DETERMINED.

4. IT WAS EXCEEDINGLY TORTUOUS AND THEREFORE COMPARATIVELY LONG DISTANCES BY RIVER WERE REPRESENTED BY VERY SHORT DISTANCES AS THE CROW FLIES, RENDERING POINTS OF OBSERVATION WITHIN EASY REACH OF ONE ANOTHER.

5. IT RECEIVED THE WHOLE OF THE SEWAGE OF THE TOWN OF SHREWSBURY.

6. WE HAD ALREADY EXAMINED THE UNPOLLUTED STREAMS OF PORTIONS OF THE WATERSHED.

The only disadvantage was that crude sewage and not an effluent passed into the river. But the bacterial problems in the two cases were closely similar, the difference lying in the fact that in the case of crude sewage the bacteria were more numerous, and that the solids passed into the river might be the means of affording a more suitable nidus for the multiplication and extension of micro-organisms. But these apparent disadvantages were nevertheless of use, because no good biological effluent could be so bad as crude sewage, and if it were found that there was no evidence of multiplication, and that the organisms did not pass far down the stream, then clearly in the case of an effluent the results would be still more satisfactory.

There have been other advantages, for the Severn has afforded an opportunity of studying the harmful effect of crude sewage pollution, and has opened up many collateral investigations directly bearing upon the question of sewage disposal.

DESCRIPTION OF THE RIVER SEVERN.

The stretch of river over which the investigations were made measured 26 miles, starting from the County Asylum, 2 miles above Shrewsbury Waterworks, and ending at Iron Bridge, 24 miles lower down. The most numerous observations were, however, conducted over a smaller length of river, viz., from the Asylum to Cressage—a distance of 18 miles. Between these points the river is exceedingly tortuous, and in passing through Shrewsbury it forms a letter S, of which the lower half nearly encircles the town. The distance between the two nearest points of the S is less than 300 yards.

The *width* varies considerably at different points, the average being about 200ft. Where broadest the river is usually shallowest, and in dry weather we found that navigation was difficult at these points even with our small boat.

The *velocity* of the river is, of course, very different according to place and season. It is great when the river is in flood, except where it is very deep, *e.g.*, just above English Bridge; and also at most times in certain definite places, *e.g.*, in Shrewsbury just above the Waterworks, through the English Bridge, through and just below the railway bridge; and at many spots below Shrewsbury.

The velocity has been estimated on two occasions at the same spot, viz., at Ferry I., by Mr. Kershaw. On July 12th, 1900, it was only 30ft. per minute, the volume at the same time being 112,000,000 gals. per 24 hours; on January 6th, 1901, 180ft. per minute, with a volume of 1,054,944,000 gals. per 24 hours. According to Mr. Masters, Engineer for the Severn Commissioners, the minimum flow (February, 1898) was 85,000,000 gals. per 24 hours.

The *height*, as will be gathered from the following measurements made at Cherry Orchard Ferry, and kindly furnished to us by the Borough Surveyor, shows very considerable variations depending upon the rainfall:—

TABLE showing Seasonal Variations in Height of River.

The *streams* entering the Severn are comparatively w. Between the County Asylum and Shrewsbury ere are none. Above the English Bridge the Rea rook, into which some sewers open, mixes its very dirty water with that of the river. With this exception, the brooks and rivulets are all, as the analyses show, comparatively clean, especially those above Cressage, viz., overflow from Sundorne Pool, near Uf-

fington; River Tern and Bell Brook, below Atcham; Cound Brook, above Cound. Below Cressage the following streams enter, viz., Sheinton Brook, Mary's Dingle Brook, "Abbey" Brook, and Hungerdale Brook. These have rather more evidence of contamination. The River Tern and Cound Brook are the only ones of considerable size.

The *land drains* are very numerous on each bank, and many of them have been examined.

THE BANKS OF THE RIVER.

Except along certain parts of the river as it flows through the town of Shrewsbury, the banks are for the most part composed of mud in which willows are numerous. The banks of the river immediately above the waterworks, and also lower down as the river winds through the town, are composed of dust-bin rubbish, which gives to an otherwise pretty river a most dirty appearance, and must be a source of considerable contamination.

THE BED OF THE RIVER.

In the neighbourhood of Shrewsbury the bed of the river is in places composed of sludge, above and below it consists of gravel or rocks. The rocky bottom gives a foothold to a very extensive growth of the Water Ranunculus.

THE SOURCES OF POLLUTION.

The Severn, in the 26 miles stretch which we have examined, affords a typical example of the way in which a beautiful river is polluted and becoming destroyed owing to the carelessness and want of knowledge of the people dwelling upon its banks.

The town of Shrewsbury draws the water which is used for domestic purposes* and which is supplied to the houses directly from the river without filtration. The intake is at a point where the river has already commenced to flow through the town; a few hundred yards lower down the town pours out, through one very large sewer and numerous smaller ones, the crude sewage of 28,396 inhabitants. As the appended map shows, there are altogether in Shrewsbury some thirty-six sewer outlets. When we commenced our investgations we were informed that there were no sources of pollution above the waterworks intake, but two miles higher up we discovered a large sewer pouring the sewage of the County Asylum, and probably of houses, into the stream. Around the outfall of this sewer, as will be gathered from one of the photographs, solid fæces could be seen floating in large quantity, and on some occasions we traced the lumps in the river as far as Shrewsbury. The bed of the river immediately around consisted of putrefying sludge.

For half a mile above the intake there are numerous houses on or close to the banks, and from many of these drain pipes of various kinds can be seen, and as previously mentioned, the banks are little else in places than dust-bin accumulations. Whilst the river passes through the town it receives, in addition to the sewage, all kinds of garbage thrown into it by those living along the banks; it also receives waste from a brewery, and from a candle factory. Thus, during the three miles of its winding course through the town it is subjected at innumerable points to contamination. From Castle Fields Ferry, which is about 2¾ miles below the waterworks, down to Uffington, 4·75 miles, there are no large sources of pollution, and the pollution at Uffington itself appears to be very small.

Lower down, at a point 10 miles from the waterworks, a large sewer enters the river; it carries the sewage of the Atcham Union Workhouse.

The little village of Cound, 3 miles further down, does not affect the river; nor at Cressage, 16 miles from the waterworks by river, although only 8 miles by road, does there appear to be any but the smallest direct inflow of impure water. From Cressage to Ironbridge is 8 miles by water, and Ironbridge is the first town on the river after Shrewsbury.

The sewage of Ironbridge and Coalbrookdale together make the river exceedingly dirty. In Ironbridge itself a multitude of sewers and drains can be seen opening either directly on to the bank or carried for a few yards beneath the surface of the water. The condition of the banks is even worse than at Shrewsbury.

In 1896 the normal dry weather flow of sewage of Shrewsbury was estimated at 844,000 gallons per 24 hours, so that the total sewage entering the river from the town may ordinarily be taken as about 1 per cent. of the volume of the stream; in dry weather the proportion of sewage would be greater.

NATURE OF THE SEWAGE.

The sewage is domestic and composed of slopwaste, fæces, paper and vegetable debris. When it reaches the river through the numerous outlets the solids and refuse are for the most part well broken down; still, a very considerable amount of the lighter fæces and pieces of disintegrated paper may be traced, as will be described further on, floating for considerable distances down stream.

Bacteriological analysis of the sewage from one of the large sewers shows that the number of bacillus coli, viz.: 300,000 per c.c., is what might be expected in a domestic sewage. Analysis of the Atcham Workhouse sewer showed on one occasion 19,000 B. coli per c.c.

EFFECT OF THE SEWAGE UPON THE BANKS, BED AND WATER OF THE RIVER.

The clearness of the river varies according to the degrees of flood. This is seen from the following summary made from observations above the town of Shrewsbury and therefore before the admixture of sewage.

		Ft.	ins.
15 November 1899	Clear, no recent rise	5	5

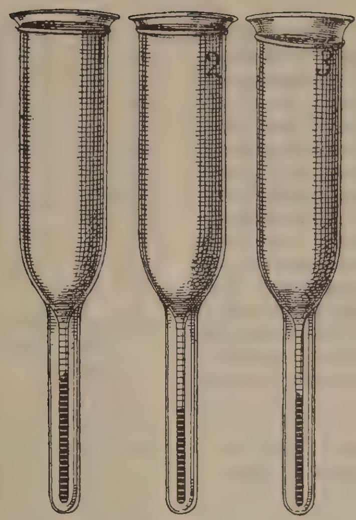
14 August "	Muddy	3	5
25 September "	Clear	1	5
18 October "	Muddy	4	0
7 December "	"	10	8

The turbidity in the above cases is due to fine mud in suspension. When the river is undisturbed the water is clear, but has the characteristic dark brown colour of water rising in a peaty watershed.

However clear the water may be above the town of Shrewsbury, the sewage of the latter place, when it reaches it, renders it turbid for a considerable distance. We have endeavoured to measure the degree of turbidity by centrifugalising a certain quantity of the water from different points and reading off the amount of solids.

* There are stand pipes in the streets which supply drinking water, which is brought from a distance, and is not derived from the river.



The Tubes employed for the centrifugal experiments.

SOLID MATTER IN SUSPENSION AND METHOD OF ASCERTAINING THEIR AMOUNT BY CENTRIFUGALISATION.

The object was to record by a simple method the increase of solids in suspension in the river which the sewage gave rise to. There is no doubt that these solids gradually settle at the bottom of the river or are thrown down upon the banks, and that they gradually form deposits. Owing to their nature they afford a nidus for putrefaction and tend to support pathogenic bacteria. The method which we adopted was very simple. A sample of water was collected by immersing a bottle below the surface of the river starting from one bank and then rowing across to the other bank in order that the sample might fairly be taken as representing a cross section of the river. 600 c.c. of the sample were centrifugalised, and the supernatant clear fluid was for the most part carefully pipetted off and the deposit together with what remained of the supernatant fluid (about 10 c.c.) transferred to a specially constructed centrifuge tube. We give a drawing of the tubes; the bottom is drawn out like a thermometer stem and graduated. The whole tube holds 10 c.c. and the graduations are definite fractions of 1 c.c. The glass is filled and centrifugalised for 2½ minutes in a hand centrifuge, making about 2,000 revolutions per minute; the result is that the deposit is forced into the graduated stem and the amount can be easily read off.

The following figures show that comparing the river at Ferry III., that is after it has received all the sewage of Shrewsbury, with the river from above the Asylum, that is before any great pollution, there is a substantial increase in solids and that although a decrease takes place from Ferry III. onwards, yet the original degree of freedom from solids is not even reached at Atcham, 11 miles, or Cressage, 18 miles further down. We shall find that the increase of solids is accompanied by similar increase in B. coli both in the mud of the banks and the bed of the river and in the water.

TABLE showing amount of Suspended Solids in 600 c. c. of River Water.

FLOATING MATTER AND EXPERIMENTS TO DETERMINE THE EFFECT OF CURRENTS UPON IT.

In addition to the turbidity imparted to the river by the sewage, pieces of macerated paper, floating debris and solid fæces, can be traced, as previously mentioned, for considerable distances. Fæcal matter is encountered collecting in recesses and bays on both banks of the river, nearly as far as Atcham. The collections of obvious sewage material along the banks of the river, and especially at certain spots, caused us to make a series of experiments to ascertain the direction in which the currents in the river were likely to take the suspended matter. Experiments were made by throwing coloured corks into the river some 12 to 15 hours before we rowed down for the purpose of taking water samples. In the first experiment the corks were thrown over the Welsh Bridge. On the following morning a few were seen to be still floating against one of the piers, being kept there by the eddies around the stonework. Elsewhere the corks had formed into groups along the banks in certain definite places. In the second experiment a much larger number of corks was thrown in, and they were found to have collected in the same places. Comparatively few remained in the stream. When thrown in at Shrewsbury no cork was seen further than four miles down on the following day; but when thrown in at Cressage there seemed to be less tendency to accumulate on the banks; many were seen in midstream, and the last one was observed at Ironbridge, eight miles below Cressage. Some may have got further, but the observation was stopped at Ironbridge. Corks were observed in the river and on the banks between Shrewsbury and Atcham, not only a fortnight and two months, but even six months after they had been thrown in; probably washed off the banks at the time the river was in flood. In the series of diagrams and photographs appended, these collections of corks are shown and indicate clearly where the solids in suspension tend to accumulate.

Investigation of the banks at these places showed that the mud was much blacker than elsewhere, and that the willows had strained out a considerable quantity of the floating material. It seems clear that most of the floating matter does not travel far along a winding stream, the banks, with their bays and willows, acting as catchpools and strainers. These are places which seriously detract from the appearance of the river and may become offensive by reason of the decomposition going on there. The changes which take place and lead to the destruction of this solid matter are similar to those taking place on a sewage farm or in aerobic contact beds. Examination of the mud at these places shows that the bacteria are more numerous, and that the bacillus coli is more abundant than elsewhere. In other words, these spots become secondary sources of pollution and danger.

THE EFFECT OF POLLUTION UPON THE BACTERIA OF THE MUD OF THE BANKS OF THE RIVER.

Thirty-two samples of mud taken at various points on the banks of the river from 20 yards above the asylum to Ironbridge, 28 miles lower down, have been examined for B. coli and B. enteritidis sporogenes. The mud was taken in sterilised bottles at the level of the water in the river. The figures which are appended (*see* Table XXVII.) show that whereas the mud above the asylum contained only 25 and 43 B. coli per c.c., the mud taken at various points along the river to Ironbridge showed abundant evidence of pollution ; in the vicinity of Shrewsbury over 100,000 B. coli were obtained in many places, and the number reached an especially high figure in the stagnant bays (432,200). From some distance above Cressage onwards to Ironbridge the B. coli was not found in 1-100th of a gramme. These analyses prove that the mud of the banks is seriously contaminated for a considerable distance below Shrewsbury (18 miles), and that some places are more highly contaminated than others.

THE EFFECT OF POLLUTION UPON THE BED OF THE RIVER AND METHODS OF ASCERTAINING IT.

The harmful changes induced in the bed of a river as the result of the entry of the sewage are well brought out in our observations. The solids in suspension tend gradually to fall to the bottom, and as time goes on they must form a considerable layer. If the water were still the deposit would be fairly uniform, as one of us (Professor Boyce) has demonstrated in the case of Lake Vyrnwy, but the velocity of the River Severn is always tending to extend the deposit further down the stream by shifting it from place to place. Our observations showed us that we found in Shrewsbury a less uniform deposit than we had anticipated, but they also revealed great accumulations.

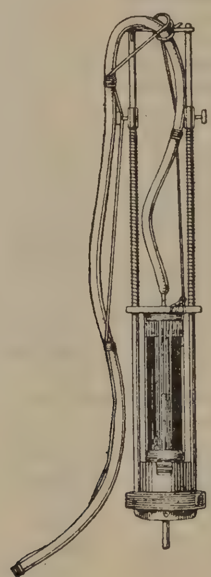

Figure of the Apparatus employed for taking samples o mud from bottom of the River.

It was apparent to the Commissioners that it was of great importance to ascertain the changes going on in the bed of the river, because it was obvious that accumulations might occur, and that these might form concealed foci for the spread of infection. We therefore devised a simple apparatus whereby we were enabled to pump with ease and accuracy into a receiver a sample of the bottom at any desirable place. The figure above of the apparatus explains its construction. A very thick india-rubber tube (pressure tubing) is attached to a glass cylinder, into which a brass tube projects for three inches. The glass cylinder is clamped in a special metal case, which is heavily weighted with lead. To the other end of the pressure tubing a small exhaust pump is attached. When it is desired to take a sample the cylinder is lowered until the latter, with its projecting brass tube is in the mud ; a few strokes of the pump readily fills the cylinder, and the apparatus is drawn to the surface. The deposit cannot fall out because of the projection of the tube in the interior of the glass cylinder. With this apparatus we have made a thorough examination of the bed of the river. We find that, as might be expected, there are great accumulations of decomposing sludge opposite the mouths of the large sewers. When the weighted cylinder presses on these filth accumulations, gas rises to the surface. The deposit around the mouth of the main sewer just below the waterworks extends for a considerable distance on each side and in front of the mouth. As the river passes through Shrewsbury and at those places where the water is shallow and the current swift, the bottom appears fairly clean, but in the deep parts, and especially at one spot just above the English bridge, the river broadens into a large pool of very considerable depth (21ft.) through which the movement of the water is slow. Here a considerable accumulation of fine sludge had collected and gas was evolved.

To estimate the number of bacillus coli in the samples taken from the bottom, the liquid mud, which was brought to the surface, was shaken up and 10 c.c. were measured out in a small cylindrical measure and weighed. The mud was allowed to settle and the proportion between mud and water ascertained. From these data the weight of mud in 1 c.c. of the shaken mixture was calculated. When the mud had settled to the bottom of the measure the supernatant water was considered to contain the washings of the mud. 1 c.c. of this mixture was taken and diluted with sterile water so as to form a dilution of 1 to 100 of the mud. This dilution was plated in taurocholate lactose agar, 1 c.c. being put into each plate, incubated at 42°C. for 48 hours and counted.

The results of the analyses agree in showing an immense increase of pollution in Shrewsbury. Above the Asylum the mud contained 70 B. coli per grm., opposite the first large sewer entering the river, the number was 300,000, a little lower 1,200,000, and in the large deep pool previously mentioned, and situated above the English bridge 44,000. By Ferry III., which is at the end of the town, the number had dropped to 5,200 and 900. Below this point the analyses opposite Uffington 6·75 miles, and Cressage 18 miles, show that the bed has not regained the condition it was in before the pollution.

These observations taken in conjunction with the analyses of the mud of the banks and the amount of

solids in suspension, show that highly polluted material is deposited for several miles along the river, and that in some places there are great accumulations. The gradual contamination of the banks and bed of the river as shown by the B. coli readings, will tend to foster putrefactive and intestinal bacteria, and to increase the pollution of the river. In flood time the loose accumulation of putrefactive material must tend to get displaced, and to get carried further down, and thus the harmful action of the sewage gradually extends.

If the banks of the river, as previously described, act as storehouses for the maintenance and gradual distribution of infected material, these deposits around the mouths of the large sewers and in the deep stagnant pools, are yet more harmful, since they are less disturbed than the banks by the scouring action of the river in flood. The deposits of suspended matter interfere with the growth of the aquatic plants; where the deposit is at all abundant there is no growth, this only making its appearance in the more shallow well-aerated parts of the river. The absence of a clean bottom, supporting weeds, will most probably act injuriously upon fish life.

We have compared the destruction of the organic matter taking place along the banks to the similar process taking place in a contact bed, similarly there is no doubt that the fermentation action taking place at certain parts of the bed of the river is strictly comparable to septic tank action. The inhabitants of Shrewsbury, as of many other places, have relied on their river to treat their sewage. There is no doubt of the deleterious effect of doing so in the neighbourhood of Shrewsbury, as shown by the appearance of the banks and the bacteriological condition of the mud of the banks and bed.

What are the effects upon the bacteria contained in the sewage both as regards the total number and the special bacteria, as those of the coli group, when the sewage undergoes, as that of Shrewsbury does, some dilution, and how far down the stream the sewage bacteria can be traced? In other words, how soon does the river, which is dilute sewage at certain spots, come back to the condition of an effluent which might be used for drinking purposes. These points will be dealt with in the following pages.

THE WATER ANALYSES.

PLACES WHERE THE SAMPLES OF WATER WERE TAKEN FOR ANALYSES.

In choosing sites for taking samples it was obviously necessary to take them above the source of contamination, at various points in and beyond, and as far as possible below the area of pollution. We do not think that there is any serious source of pollution above the "Asylum sewer," until Welshpool is reached, some twenty miles higher up. The first sample was consequently taken about 100 yards above the sewer outfall, and another about the same distance below.

Four points in the town were selected: (1) At the waterworks intake, (2) "Ferry I." at the Quarry, (3) just below the English bridge, viz., after the large contamination caused by Rea Brook, (4) "Ferry III." at Castle Fields, the lowest limit of houses on the bank; within these four points, which are on the lower loop of the above-mentioned S, all the town sewers (with one exception), 36 in number, enter. The other places selected further down the river, were Uffington, Atcham, Cound, and Cressage, and on three occasions, Buildwas and Ironbridge.

Sometimes samples were taken at other places, and in a few instances both above and below small villages like Uffington, etc., to determine whether they had any effect. The names and positions of the other places are given on the tables. The standard places are as follows:—

Distance from Waterworks. Miles.	Name of Place.
2	Above Asylum sewer outfall, 20 yds.
2	Below " "
—	Waterworks.
0·6	Ferry I.
1·6	English Bridge.
2·5	Ferry III.
4·75	Uffington.
9	Atcham.
13	Cound.
16	Cressage.
21·5	Buildwas.
23·5	Ironbridge.

The method of collecting the samples of water from time to time has varied. On three occasions in November, 1899, the samples were taken from ferries or bridges. Only one sample was taken at any one point, and, although three were taken across the river, viz., midstream, right and left banks, these were not mixed, but were analysed separately.

From January, 1900, onwards the samples were taken from a boat, usually in midstream about 2ft. 6in. below the surface of the water. From April onwards six or more of these "deep" samples were collected at any cross section of the river and mixed, and the mixed sample analysed. At the same time a midstream sample was also taken and separately analysed for comparison. In July and afterwards both superficial and deep cross section samples were taken. On the last two occasions both superficial and deep samples were taken simultaneously. Prior to that it was necessary to row twice across the river, and in consequence the samples may not be strictly comparable. In any case it may be doubted whether the results are so trustworthy as a midstream sample, because it is practically impossible to avoid a disturbance of the river bed when getting near the shore.

When first the boat experiments were started it was thought necessary simply to let it drift in order to obtain concordant results, but it was soon seen that this was not really necessary nor practicable, because the boat does not drift so fast as the lighter suspended solids, and it would have extended the experiment through the night (not a very safe proceeding or a shallow river like the Severn), and delayed the examination of the samples.

Only one analysis has as yet been made of the water taken from one place (Cressage Bridge) at definite intervals during the day.

The small bottles used for collecting were kept in an icebox until our return to the laboratory in Liverpool, the same evening, when they were put into the refrigerator room and kept there until the time of examination on the following morning.

METHODS OF BACTERIOLOGICAL ANALYSIS EMPLOYED.

The object of the analyses was to ascertain the total number of bacteria present, the number of the bacillus coli group and the presence or absence of the bacillus enteritidis sporogenes. To ascertain the former numbers, Petri dish cultivations were made. The media used consisted of standardised gelatine, and carbol and bile salt agar. The carbol agar was carefully prepared, and of such strength that when 1 c.c. of the water to be analysed was added to 9 c.c. of the carbol agar the strength of the carbolic acid was 1 in 1,000. This strength Miss Chick had determined by a lengthy series of experiments, published in the Thompson Yates Reports, to be best adapted for isolating the B. coli group. With this strength of carbolic acid a very large proportion of the common putrefactive bacteria were inhibited, so permitting of the more ready identification of the coli group. Later on in the experiments the carbol medium was replaced by Taurocholate Lactose Agar.

The composition and advantages of this medium for the detection of the B. coli and typhoid baccilli have been separately reported upon to the Commissioners, and need not again be detailed. Previous to making an analysis the bottle containing the sample was carefully shaken, and 1 cubic centimetre, or a definite dilution of this (1 in 10, 1 in 100, 1 in 1,000, etc.), added to the liquefied gelatine and agar tubes. In the case of gelatine, six Petri dish cultivations were made, in the case of agar three. The former were incubated at 20° C., and examined from time to time till they showed the maximum number of colonies. The agar plates were incubated at 42° C., and first observed at the end of 48 hours.

To determine the presence of the B. enteritidis sporogenes, freshly prepared sterilised milk tubes were used. When the water to be examined, either undiluted or diluted in the proper dilution, had been added to them they were exposed for 15 minutes to 80° C. in a water bath, and then incubated at 37° C. with anaerobic precautions.

Owing to the large number of analyses made, and the uniformity of the media, the figures which we have obtained are as accurate as these forms of analysis can be.

Examination was also made for special bacteria such as thermotletic and H_2S forming bacteria; for the cultivation of the latter ferro-gelatine was used.

THE BACTERIOLOGICAL ANALYSES OF THE RIVER SEVERN ABOVE THE SOURCES OF POLLUTION AND OF THE LAND DRAINS AND STREAMS ENTERING IT.

One of the large tributaries in Wales which go to form the River Severn is the River Vyrnwy.* The watershed of this river has been formed into a very large artificial lake by means of a dam, but a regular flow of water from the lake, known as "compensation water," is allowed to flow away, in order to maintain the River Vyrnwy in the condition it was before the construction of the lake. The lake is one of the main water supplies for Liverpool, the water being first carried to Oswestry, where it is filtered. This lake and the numerous streams entering it, as well as the soil of the watershed and the mud which settles to the bottom of the lake, are constantly under observation. The analyses are made regularly for the Corporation of Liverpool by one of us (Professor Boyce). The comparison of the results of the analyses of the unpolluted Vyrnwy watershed and of the polluted Severn lower down are very striking, and clearly demonstrates the value of the bacteriological analysis, and of the importance of the B. coli as a test of intestinal contamination. The following is a summary of the results on the watershed.

Streams of Lake Vyrnwy Watershed.

Thirty-eight streams entering the lake were most carefully analysed by Miss Chick † for the presence of the B. coli. The latter was found only in one case present in 1 c.c., and in this case "there was a gang of men working close to this stream on this date." In two other cases it was present in a less proportion than one B. coli per c.c., and here again, owing to proximity to farms, there was probability of contamination.

Samples of Soil of Watershed.

Fifteen samples of soil were analysed by Miss Chick. "One gramme of soil was weighed into a sterile flask, 10 c.c. of sterile water were added in some cases, and 50 c.c. in others. The whole was then thoroughly well shaken, and 1 c.c. taken and 3 plates poured." The B. coli was absent in the quantities taken, viz., 0·1 grm. and 0·02 grm.

Water of the Lake.

The water has been repeatedly analysed for the past three years, and one cubic centimetre has been found free from B. coli. Larger quantities have, however, been shown by Miss Chick to contain this organism in small numbers. The average number of bacteria, as determined at different points on the surface, and at various depths in the lake is 31 per c.c.

Deposit on the Bottom of the Lake.

A thorough examination of the bottom of the lake has been recently made by us with the apparatus previously described. In all, 28 samples of mud were brought to the surface from depths varying from a few feet to 70 ft. The method of analysis consisted in adding ·5 c.c. of the mud to two taurocholate lactose agar tubes, and making two Petri dish determinations. The investigation showed that in the comparatively large sample of mud taken from very numerous points in the bottom of the lake, the bacillus coli was found in three samples and then only one colony was present in each case; thus bearing out the preceding statements with regard to the absence of the B. coli from the streams, and from the lake of the Vyrnwy watershed.

The Bacteria of the Land Drains and Small Streams entering the Severn between Shrewsbury and Cressage (18 Miles).

We found numerous land drains entering the river between the Asylum (Shrewsbury) and Cressage. The water of these, with one exception, viz., the Atcham Workhouse sewer, was perfectly clear. Seventeen of these have been examined for the B. coli by the carbol agar method by Miss Chick.

In twelve cases the B. coli was absent in 1 c.c. Where present it was only in small numbers, and in these cases contamination might be suspected from their proximity to houses. The comparative freedom of land drains from B. coli is a most noteworthy fact, and demonstrates that these small tributaries are harmless unless they receive sewage.

The analysis of one particular small land drain proved in a remarkable manner the truth of this statement. As many as 19,000 B. coli per c.c. were found in it; we then traced it back from the river, and observed that it received the sewage of the Atcham Workhouse, we also discovered the other unmistakable sign of sewage pollution in it, viz., the presence of abundant growths of Sphaerotilus natans. The total number of bacteria per c.c. in these drains varies between 100 and 3,000, and this is what might be expected from the absence of the *B. Coli.*

In addition to the land drains an investigation was made of the small brooks entering the river. A table is appended showing that 17 analyses were made (Table XXV.). It will be seen that the total number of bacteria are greater, and that the bacillus coli was usually present, the average being 24 per c.c. From the position of these brooks we concluded that they must all have been contaminated.

The Bacteria of the Severn immediately above Shrewsbury.

The samples were taken about 20 yards above the county asylum sewer outfall, and therefore 2 miles above Shrewsbury. A table is given showing the result of bacteriological analyses extending over one year. The total number of bacteria appears to vary considerably, the average working out at 10,000 per c.c., but if certain very abnormally large enumerations were left out, and which appear exceptional, the average would not exceed 5,000 per c.c. The bacillus coli is usually present, but only in small numbers, the average being 11 per c.c. The bacteriological state of this part of the river, which here is about 180ft. broad, is better than the small brooks entering it, and this is what would be expected, because the river starts with a considerable volume of unpolluted water.

SUMMARY OF THE RESULTS OF THE BACTERIOLOGICAL ANALYSES OF THE RIVER SEVERN AND TRIBUTARIES PREVIOUS TO POLLUTION.

Commencing with the watershed the numerous analyses which have been conducted during the past three years show that the B. coli is absent in the proportion of 1 per c.c. in the feeders of the River Vyrnwy. An extensive analysis of the mud of the lake, and of the soil of the watershed also shows the absence of the B. coli. The watershed is the property of the Liverpool Corporation and is carefully protected from pollution, and the results show that in the absence of fæcal contamination there is no B. coli.

Next proceeding to the Shrewsbury district which is not under control in the same manner as the watershed, we find that the numerous small brooks which enter the Severn reveal evidence of definite contamination, but that the land drains, the water of which is probably subjected to some slight degrees of filtration, are comparatively free from pollution. This is very interesting for undoubtedly the brooks are liable as they pass close to human habitations to contamination; whilst the land drains, removing the water from pasture and arable land are isolated. Lastly, taking the River Severn itself above the great source of pollution which occurs at Shrewsbury, we find that B. coli is present in the proportion of about 10 per c.c. Between Vyrnwy and Shrewsbury there is a gradual contamination, every brook which contributes to the volume of the Severn as it passes through the more thickly peopled districts, adds a small number of B. coli, and at certain places like Welshpool there is considerable direct contamination. No wonder then that already above the waterworks intake at Shrewsbury there is distinct evidence of sewage pollution. Thus the streams of the watershed may be taken as the standard of purity and as furnishing water which is harmless to drink; that of the Severn above Shrewsbury as slightly polluted, and as water which should be subjected to filtration before being consumed. It remains now to see what is the effect of turning the sewage of Shrewsbury into the

* One of us (Professor Boyce) has rowed down the Severn from Welshpool, which is the first navigable point on the river, and which is between 50 and 60 miles above Shrewsbury by river. There is marked coli pollution at Welshpool, and this gradually disappears.

† The distribution of the B. coli. Harriette Chick B.Sc. Thompson Yates Reports, Volume III. Part I., 1900.

already slightly polluted river, and how far it differs bacteriologically from the standard in the watershed after it has been polluted, and further after what distance it regains its original degree of purity.

EFFECT OF THE POLLUTION OF SHREWSBURY UPON THE WATER OF THE RIVER SEVERN.

As stated earlier in this report the places where the samples were taken for analysis were as follows:—

1. Opposite the County Asylum, that is a point 2 miles above the Shrewsbury Waterworks.

2. Opposite the Waterworks intake, which is situated just inside the town of Shrewsbury.

3. At "Ferry I." (Quarry Ferry), 0·6 of a mile lower down.

4. At English Bridge, 1·6 miles from the Waterworks.

5. At "Ferry III." (Cherry Orchard Ferry), 2·5 miles from the Waterworks. This point marks the end of the town of Shrewsbury, the polluting area being comprised between the Waterworks and this point.

6. Uffington, a village 4·75 miles below the Waterworks.

7. Atcham, a village 9 miles from the Waterworks.

8. Cound, a few houses, 13 miles from the Waterworks.

9. Cressage, a village 16 miles from the Waterworks, or 18 miles from the starting point.

Occasionally samples were taken at the village of Buildwas 21·5 miles from the Waterworks, and Ironbridge a town 23·5 miles from the same point.

It is not necessary to repeat the methods of analysis we employed, these will be found in the commencement of the report. Those who are practically acquainted with river analyses will know the difficulties of obtaining strictly accurate results. By repeating our analyses and by making several analyses from each sample, and by always keeping the samples on ice we believe that our results give a very true picture of what is happening bacteriologically in the river.

THE TIME OF THE YEAR WHEN THE ANALYSES WERE MADE.

The first analyses were made in the month of November, 1899, others in January, March, April, May, July, August, September, October, November, and December in 1900, and a few in February and March of this year 1901. The analyses have therefore been made throughout one whole year, in spring, summer, autumn, and winter, and in all conditions of the weather, and with the river at its highest and lowest levels.

OBJECT OF THE BACTERIOLOGICAL ANALYSES.

To determine the total number of bacteria per c.c., the number of the bacillus coli communis and the proportion of the bacillus enteritidis sporogenes as measured by its spores. Numerous determinations were made of the number of thermophilic bacteria present. The general bacterial flora of the river was also investigated.

RESULTS.

Two series of tables are appended to this report; in one series the analyses are grouped under the place where each observation was made (Tables I.-VIII.); in the other series of the analyses of the stretch of river examined on a given date are recorded (Tables IX.-XXIV.).

In order to render the tables more intelligible graphic charts have been prepared which show at a glance the bacterial state of the river in the various months of the year as well as the average.

I.—TOTAL NUMBER OF BACTERIA (ROUND NUMBERS).

At Asylum *	the average is	7,000 per cc.	0	miles.
„ Waterworks	„	13,000 „	2	„
„ Ferry I.	„	20,000 „	2·6	„
„ English Bridge	„	23,000 „	3·6	„
„ Ferry III.	„	19,000 „	4·5	„
„ Uffington	„	17,000 „	6·75	„
„ Atcham	„	13,000 „	11	„
„ Cressage	„	5,000 „	18	„

A glance at these figures and at the large charts (Charts I. and II.) shows that the effect of contamination is unmistakable. Already before the Waterworks are reached the numbers have increased, owing to the pollution which was pointed out to occur for some distance above the Waterworks intake.

In the midst of the pollution at English Bridge the number of bacteria has reached a maximum; they are more than three times more numerous than at the start. From Ferry III., that is the end of Shrewsbury, there is a gradual drop for two miles below this point, for at Uffington the number is 17,000, and at Atcham six miles further down the number is 13,000, finally at Cressage, 13 miles below the last source of town sewage contamination, the number is even lower than that at the Asylum above Shrewsbury.*

At first sight the results might appear remarkable. The effect of pollution as measured by the total number of bacteria does not appear so large as might have been anticipated, knowing as we do that all the sewage of a town of some 28,000 inhabitants enters the river and that the average number of bacteria per c.c. in such sewage is about 3 millions.

Dilution is the cause of this large reduction; the volume of the River Severn is more than 100 times greater than that of the sewage entering it and the effect of this is to reduce the numbers to a figure on the average below 30,000 per c.c. The other remarkable feature is that the bacteria are not carried down so far as might be expected, for at least at Cressage 13 miles from Shrewsbury it cannot be said that the effect of the sewage can be measured by the total number of bacteria present in the water. These observations are in accord with those of other investigators, as will be seen from the table appended, showing the results of analyses of some rivers on the Continent (Table XXX., p. 14).

II.—TOTAL NUMBER OF BACILLUS COLI.

Our investigations have in the main differed from those of previous investigators in the attention which we have directed to ascertaining the numbers of this micro-organism both in the water and in the mud of the banks and bed of the river. As previously pointed out, we have, as the result of our own investigations, come to the conclusion that this organism is a most accurate measure of intestinal pollution, and that far greater information as regards the effects of sewage pollution can be gathered by its estimation than by simply counting the total number of organisms present. We know a great deal more of the B. coli than of the innumerable other bacteria which are found in water and in sewage, and which from various causes may undergo considerable fluctuations in their numbers in their course down stream. The Bacillus coli is an intestinal parasite, and away from the intestine it is not, in the great majority of cases, in a suitable medium for its multiplication, and tends to perish, and therefore if it is found it has not been long absent from the intestine.

The average figures obtained are as follows:—

	B. Coli.		
At Asylum	13 per cc.	0	miles.
„ Waterworks	46 „	2	„
„ Ferry I.	177 „	2·6	„
„ English Bridge	321 „	3·6	„
„ Ferry III.	600 „	4·5	„
„ Uffington	142 „	6·75	„
„ Atcham	48 „	11	„
„ Cressage	36 „	18	„

These figures and the chart (Chart II.) made from them show more strikingly than the preceding enumerations the effect of pollution and the distance at which the pollution is felt.

As in the case of total numbers so here there is a slight increase at the waterworks, and from thence a rapid increase takes place for the three miles the river winds through Shrewsbury to Ferry III. At this point the average number of B. coli per c.c. is 600, or 46 times greater than in the water above Shrewsbury, whilst as seen in the case of the quantitative analyses the maximum average was only three times greater than in the unpolluted water. The maximum effect of pollution occurs at the end of the town, where one would expect it to be. Two miles further down (Uffington) the

* It is highly probable that this average is misleading, for, with one exception, on each day when samples were taken both at the Asylum and at Cressage, the numbers at the former spot were much lower than at the latter.

number has dropped very considerably; at 6 miles (Atcham) the number is 48, and at the 13 miles point (Cressage) the number is 36 per c.c.

As the result of allowing the sewage of Shrewsbury to enter the river, there is at once nearly a fiftyfold increase in the numbers of this intestinal parasite, and a river which two miles higher up (at the Asylum) only contained a few to the cubic centimetre, and still higher up in the unpolluted sources in Wales contained none to the cubic centimetre, now contains upon an average 600 per c.c. But here again a larger number of B. coli might have at first sight been expected, but when it is remembered that the average number of B. coli in sewage varies between 50,000 and 100,000 per c.c., and that the sewage becomes diluted at least 100 times, the above figures appear correct. After the pollution ceases the number of B. coli falls very considerably, showing that there is no multiplication, but even at Cressage, 13 miles lower down, the effect of the sewage of Shrewsbury can be distinctly seen. Our observations, indeed, lead us to the conclusion that the effect of Shrewsbury pollution has not had time to disappear before another town, viz., Ironbridge, pours its sewage into the river. It is in this way that rivers become gradually polluted from source to mouth, and that a river eminently potable at its commencement, becomes unfit for drinking purposes lower down.

The analyses show that there is no evidence of the multiplication of the B. coli in the water. These organisms removed from their most favourable environment in the animal body find conditions in the river unsuitable to their multiplication, and they probably perish in considerable numbers as they pass down stream. But most probably the greatest cause of their removal is sedimentation and adhesion to the mud of the banks.

We have proved their presence in considerable quantities in the mud of the bottom and of the banks. (Tables XXVII. and XXVIII.) Here, however, as already pointed out, although they do not perish immediately, owing probably to the food conditions being more favourable, there does not appear to be any evidence of multiplication. As pointed out in a previous report upon the "Filtration of Sewage Effluents," we could not find any evidence of the multiplication of the B. coli in the body of the sand or earth filters, and we concluded that filtration, and the struggle for existence with the other organisms, and the products of these, and in addition the fact that the physical conditions of temperature, food, etc., were not like those in the alimentary tract, were the causes of their reduction. So in the case of the river, sedimentation, unsuitable environment, and struggle for existence with other organisms help to extinguish it. But these observations teach us that accumulations may gradually occur, and that when the river is disturbed these may considerably augment the numbers, and, further, that even 13 miles below Shrewsbury there is distinct evidence of pollution.

THE SIGNIFICANCE OF THE BACILLUS COLI IN THE RIVER.

It is often argued that the presence of the B. coli is of little significance, because it must be widely distributed in nature, and because it must often be taken internally in water and food stuffs. But we have shown by very numerous analyses that the B. coli is not universally distributed, and that it occurs in foods and water in those cases where pollution might obviously have taken place, and the recent report of the German Commission confirms our conclusions as regards the sudden rise of the B. coli in streams flowing in the neighbourhood of human habitations. Therefore we conclude that in the first place the B. coli serves as a most unmistakable indicator of intestinal pollution, and that as seen from our river experiment the degree of pollution can be accurately measured at any given point. Measuring intestinal pollution, and, moreover, intestinal pollution of recent origin, as we have shown elsewhere, it may be taken as a guide of what would happen to the bacillus typhosus or cholera vibrio if these organisms escaped into the river.

In our Colonies and in India, as previous Commissions have shown, polluted water is a fertile source of cholera, but in this country the danger of drinking impure water arises largely from the presence of the bacillus typhosus. If in the case of the River Severn the B. coli which we have found in such comparatively large numbers after the sewage of Shrewsbury has passed into it was replaced by the B. typhosus, we would unhesitatingly conclude that the organism would be carried very many miles down stream, and that it would collect in the mud of the river. Fortunately, it is never so abundant as the B. coli, a fact which will be readily understood when it is recollected that the proportion of typhoid cases is in most instances comparatively small. It will be seen that in the case of Shrewsbury an epidemic of typhoid which would affect one-sixth of the inhabitants would only lead to the presence of about 100 B. typhosus per c.c. in the river at Shrewsbury, and that although these might be carried down several miles, yet as seen from the B. coli observations the chances of this would be small. There can be no doubt that the great volume of the River Severn thus greatly reduces the risk of the transportation to any distance of the pathogenic organisms. Our observations tend to show that it is the small polluted stream like the Atcham brook, containing perhaps 19,000 B. coli per c.c., and which if drunk or used for washing utensils might very well convey the infection of typhoid. In other words, if the sewage, however small in quantity, that derived, for instance, from only one cottage, enters a very small brook (or percolates into a well), which is drunk within a short distance of the source of contamination, the chances of infection with typhoid, if there was a case of this disease in the house, would be great. These observations, based upon the often far larger proportion of B. coli in small streams than in larger rivers, accords with the experience of typhoid infection through wells.

From what has been said, no doubt ought to exist of the value of the B. coli as a measure of the degree of intestinal pollution, and therefore of the chances of the presence or absence of the B. typhosus. But the presence of the B. coli may itself be harmful. We have found it associated as others have done with outbreaks of diarrhœa and inflammation, and with abscess formation.

The bacillus coli taken in by the mouth may produce serious results. Having before them this fact, the Commissioners asked us to test the pathogenicity of the B. coli, which we isolated. It was found that in the majority of cases the organism was not pathogenic when introduced subcutaneously into the guinea pig.

This is quite in accordance with our knowledge of pathogenic organisms; removed from the animal body they rapidly lose their virulence, but once introduced into the system they may at any moment become pathogenic. If it is satisfactorily established, and we have endeavoured to do so, that the B. coli which is found in the River Severn is derived largely from the B. coli of the intestine of the inhabitants of Shrewsbury, then certainly this organism, when it is taken in by the mouth and reaches the small intestine, may become pathogenic, as Dr. Klein has pointed out in his evidence before the Royal Commission.

NOTE UPON THE DEFINITION OF THE BACILLUS COLI GROUP.

We have considered it necessary in view of criticism of the results which we have obtained with the B. coli to summarise here our investigation of this group.

Numerous organisms have been described, under different names, which really belong to the same family and merely show insignificant variations from the original type. Experience has shown us that these variations are not constant, and consequently are not to be relied upon. Instead, therefore, of attempting to identify with its special variety every organism which we have isolated we have endeavoured to gather them together in groups and to differentiate the groups by reactions which are constant. One example of our method will suffice.

A subculture of the original B. coli communis (Escherich) was obtained and worked out. It had the following biological characteristics.

Morphology.—A non-sporing, slightly motile organism usually short but with many long forms.

It does not liquefy gelatine, and does not stain by Gram's method.

Bile salt-Glucose broth	Acid and gas.
Glucose broth - -	,,
Lactose broth - -	,,
Mannite broth - -	,,
Cane-sugar broth	- No change.
Indol - - -	- Usually present, but not always.
Milk - - -	- Acid and clotting.
Agar and Gelatine	- Moist, whitish, or greyish growth, showing nothing characteristic.

Now the characters which so far have been shown to be constant are :—

(1) The non-formation of spores.

(2) The non-liquefaction of gelatine.

(3) Acid production in milk.

(4) The reactions in the various sugars.

Under the following heads, however, variations do occur :—

1. *Gram's Method.*—As regards the staining by Gram's method, Alexander Schmidt has found that under certain circumstances members of the B. coli group retain Gram's stain. Too much stress must not, therefore, be laid upon the fact that if an organism stains by Gram it cannot be a member of the Coli group.

2. *Milk.*—The coagulation of milk is also somewhat unreliable, as we have isolated organisms which at first coagulated milk, but later did not, and vice versa.

3. *Indol.*—The production of indol is very variable. The same organism will sometimes give the indol reaction, and sometimes fail to give it. The production of indol apparently depends upon some unknown quantity in the broth, and as broth cannot be made of exactly the same composition each time we consider that little importance should be attached to this reaction.

4. *Cane Sugar Broth.*—It will be noticed that the B. coli (Escherich) does not cause any change in this medium. Organisms have been, however, isolated which correspond in all other particulars with B. coli communis (Escherich), but which caused changes in Saccharose broth. Consequently we are at present in doubt as to the real value of this medium.

5. *Motility.*—This is another doubtful point, for the B. Neapolitanus gives the reactions of the group, and yet is, so far as is known, non-motile.

6. *Flagella.*—The *Bacillus coli* (Escherich) has usually 4 to 8 flagella attached all round the organism, but B. C.C. forms have been described with only one terminal flagellum.

For the above reasons then we would for the present define the B. coli communis group as consisting of organisms which have the following characters :—

(1) THEY ARE NON-SPORING AND NON-LIQUEFYING.

(2) THEY RARELY STAIN BY GRAM'S METHOD.

(3) THEY PRODUCE ACID AND GAS WITH BOTH GLUCOSE AND LACTOSE, AND MAY DO SO WITH SACCHAROSE.

(4) THEY PRODUCE ACID IN MILK. AND USUALLY ALSO COAGULATE IT.

(5) THEY PRODUCE ACID AND GAS IN BILE SALT GLUCOSE BROTH.

(6) THEY GROW WELL AT A TEMPERATURE OF 42° C.

We would, therefore, include in the B. coli communis group such organisms as

B. Neapolitanus (Emmerich).

B. Acidi Lactici (Hueppe).

B. Cavicida (Brieger).

B. Capsulatus (Pfeiffer).

Some organisms, such as B. pyogenes fœtidus, give all the reactions of B. coli communis except gas production. The position of these organisms is at present doubtful.

Another group which suggests itself is the "*Gaertner*" *group.*

It includes such organisms as the

B. Enteritidis (Gaertner),

B. Psittacosis (Nocard),

B. Choleræ Suum (Flexner),

and differs from the B. coli communis group in causing no change in lactose or cane sugar, and in not clotting milk, but resembles B. coli communis in its power of producing acid and gas in glucose and mannite media.

A third group is the "*typhoid*" *group*, which produces only acid with glucose and mannite, and does not affect lactose or cane sugar. In milk there is either no change or only a slight acid production.

COMPARISON OF THE TOTAL NUMBER OF BACTERIA WITH THE NUMBERS OF B. COLI.

The proportion of B. coli to the total numbers is well seen in the large chart (Chart I.), where both are figured out on the same scale. This chart shows very clearly that the B. coli forms only a small fraction of the total numbers, and that the increase in numbers is accompanied by a corresponding rise in the Colon bacillus. There are, however, certain small differences of agreement; for instance the total number of organisms is greatest at English Bridge, whilst B. coli is greatest a little further down at Ferry III., and at Cressage the numbers of B. coli have not dropped in the same proportion as the total numbers. (*See* footnote, p. 9.)

SEASONAL VARIATIONS IN THE NUMBERS OF BACTERIA.

The total number of organisms in the river differs according to meteorological conditions. When the weather is dry and warm, and the river low, the numbers are above the average. This is well seen on September 25th, 1900, when the river was at its lowest. On the other hand on January 11th, 1900, the river was high, and the temperature low, and the numbers are decreased. When the river is muddy the total number is somewhat increased. When the river is swollen and the sewage in consequence greatly diluted the number of B. coli is considerably reduced (Charts III. and IV.).

DIFFERENCES BETWEEN SUPERFICIAL AND DEEP SAMPLES.

The differences between the samples collected on the surface and those taken 2ft. below the surface do not appear great. More commonly the superficial contains more bacteria than the deep sample, but in many instances this is reversed.* (Chart V.) We may here point out as an explanation of the irregular rises in numbers which are sometimes noticed, that the presence of a small particle of fæcal or decomposing matter in the water analysed may greatly augment numbers. It is always necessary to repeat observations many times.

THE EFFECT OF CURRENTS UPON THE DISTRIBUTION OF BACTERIA. STAGNANT BAYS.

The cork experiment which we devised showed clearly that floating bodies tend to pass out of the stream and to collect in certain bays and stagnant recesses along the banks. We found the mud of these bays very dirty and containing considerable quantities of the B. coli. Usually the water here presented a scum, and contained very large numbers of bacteria, and on this account in taking our cross section samples of the river we avoided these pockets. We also took numerous samples from the middle of the stream, and close up to the banks, and sometimes the one and sometimes the other contained the larger number of bacteria. From these experiments and from the superficial and deep analyses we concluded that the bacteria in the river showed an irregular distribution, and it was for this reason that in the later observations a series of samples were taken, as described in the early part of this report, at numerous points from bank to bank, and then mixed, and the samples for analysis drawn from the mixed samples. This is a method which we strongly recommend to be carried out in all future analyses of rivers. In the preceding pages attention was drawn to the possible dissemination of bacteria from accumulations of mud and debris in certain bays along the sides of the river; and that this is very probable will be gathered from the fact mentioned above, that the bacteria in the water in these places are very abundant.

B. ENTERITIDIS SPOROGENES (KLEIN).

Considerable importance has been attached to this bacillus by Klein and Houston on account of its supposed causal relation to certain outbreaks of epidemic diarrhœa, its presence in comparatively large numbers in sewage, and its absence from pure water and virgin soil. For these reasons they consider its presence to

---

*As the result of an exhaustive investigation in the Rhine, Salomon found as a mean of 176 superficial samples 3,975 colonies per c.c. ; of 192 deep samples, 4,642 cols. per c.c. ; but he also found that the individual analyses were very variable.

indicate previous sewage pollution. The identification of the bacillus is not always easy without recourse to an inoculation experiment, since according to Klein it may be confounded with B. butyricus and B. cadaveris, the main difference lying in its pathogenicity to guinea pigs. If this be so, then it is not such a reliable indicator of sewage contamination as B. coli, for, firstly, it was absent in many samples of the River Severn taken at points where the river was obviously contaminated with sewage and B. coli communis was found; secondly, several of the samples which gave an apparently typical reaction in milk culture were very slightly, if at all, pathogenic. Moreover, from recent investigations by Balfour Stewart and Glynn (Thompson Yates Report, Vol. III.), confirmed in some details by Klein and Houston (L. G. B. Report, 1899-1900), it is evident that this bacillus, pathogenic to guinea pigs, is very widely distributed. Not only did they find it, as previous observers have already done, in the normal and diseased intestine—the normal habitat of B. coli—but also in various foods, cooked and uncooked, in dust, and occasionally in air, *i.e.*, places in which B. coli was practically always absent. It is, therefore, much more widely distributed than B. coli, but this is not surprising, since it has been shown by Miss Chick and others, that drying and sunlight rapidly destroy B. coli, while the more resistent spore-bearing B. enteritidis survives. Consequently without denying that the original habitat of B. enteritidis is the intestine, and that its presence indicates previous pollution, it is evident that we are constantly ingesting it to a far larger extent than B. coli, that it normally occurs in foods in which B. coli is absent, and for these reasons we cannot attribute to it the same diagnostic importance.

As regards its distribution in the River Severn, it has usually been absent when B. coli was absent, namely in the comparatively pure parts of the river, and in some of the land drains entering it; on the other hand it has occasionally been absent also in obviously polluted parts like Cherry Orchard Ferry, so that its distribution forms a most irregular curve.

The method adopted for the detection of B. enteritidis was that originally recommended by Klein, viz., anaerobic cultivation in freshly sterilised milk. It may, however, be added as a matter of general interest, that, no difference could be detected between these and control cultivations made without anaerobic precautions.

In conclusion, although it is of considerable interest to demonstrate the presence of this remarkable spore-bearing anaerobe described by Dr. Klein, yet we do not think that it is necessary to make a routine application of this test, and we note that it has not, so far as we are aware, been employed by continental observers in bacteriological analysis, although known to them for the last four years.

THERMOPHILIC AND THERMOTLETIC BACTERIA.

The bacteriological investigation of the River Severn could hardly be considered complete without some investigation into this class of bacteria, especially since they are usually absent from 1 c.c. of good water, but elsewhere are very widely distributed, although, as a special investigation showed, absent from many foodstuffs. They are always found, in varying numbers, in the River Severn, and although one form seemed especially present in the contaminated area, its distribution was not sufficiently characteristic to be of much use. Most of the forms isolated were non-pathogenic for guinea pigs; one bacillus was pathogenic when grown in milk culture. We do not think in the present state of knowledge that much use can be made of these observations, but they suggest that the presence of thermophilic bacteria in large numbers is to be regarded with suspicion.

The method adopted was simply to make agar plate cultivations with 1 c.c. of water (or less, of sewage), and to incubate at 55°-65° C. Subcultures were then made and examined. Several forms were theremotletic (heat-enduring) rather than thermophilic (heat-preferring), inasmuch as they grow quite as well at 37° C.

THE BACTERIAL FLORA OF THE RIVER SEVERN.

The adjoining table gives in brief the characteristics of 75 organisms isolated from gelatine plates of the water of the River Severn. The samples of water were taken at various points of the river during its passages through and beyond the town of Shrewsbury. Before the untreated sewage of the town enters the river, the most characteristic organisms which occur are the fluorescent liquefying bacilli and chromogenic or non-chromogenic cocci. After the entrance of sewage these tend to disappear, and their place is taken by the common and yellow Porteus forms—types of organisms commonly found in sewage-polluted waters (together with bacilli conforming to the types of B. Ramosus and B. Megaterium).

The most characteristic and the most frequently occurring were isolated from the plates. The classification adapted is that of Professor Marshall Ward in his fifth report to the Water Research Committee of the Royal Society, and one adapted by us in an investigation of the micro-organisms found in the Liverpool waters. (Journal of Path. and Bact., May, 1899.) Considering in detail the adjoining table, the following are the groups, members of which were isolated :—

Group 5. Colourless non-liquefying bacilli, conforming to the type of B. Coli Communis.—Three of these were typical of and gave all the reactions of B. Coli; the fourth, though microscopically identical with the the others, did not act on milk, or ferment glucose, probably an enfeebled form.

Group 6. Common Proteus Type.—This is ver y common—18 organisms were isolated—all act upon milk, lotting and peptonising the casein, some giving an acid, other an alkaline reaction to Litmus. They all form indol in broth, but only a few are capable of fermenting glucose.

Group 7. The Yellow Proteus Type. The members of this group also are found to occur very commonly, and are characterised by rapid clotting and peptonising action in milk, with an acid re-action. The majority give idol in broth, but are not capable of fermenting glucose; they are apparently closely allied to the fluorescent bacilli, from which they are difficult to distinguish.

Groups 9 and 10. Yellow Liquefying and Non-liquefying Bacilli.—7 examples.—Probably a variety of Group 7, which they resemble closely in their reaction.

Group 13. Bacilli producing a crimson pigment.—This type is uncommon—only one example being isolated. It is probably identical with B. prodigiousus.

Group 15. Bacilli conforming to the type of B. Subtilis.—This type is frequently met with, but only two forms were studied in detail.

Group 16. Sacrinæ forming a Yellow Pigment.—This is fairly common; the liquefactive action in gelatine is not constant.

Group 19. Non-chromogenic Micrococci.—These are found to occur very frequently. 19 examples were isolated. Only two of these were capable of acting on litmus milk, producing an acid re-action. Microscopically they were all staphylococci.

Group A. Chromogenic Micrococci.—Fairly common, 7 specimens isolated. Only 2 were capable of changing litmus milk. Their microscopical appearances varied slightly in different specimens.

Group C.—A pure yeast form.

COMPARISON OF THE BACTERIOLOGICAL ANALYSES OF THE RIVER SEVERN WITH THOSE OF OTHER RIVERS.

Investigations on the self-purification of rivers have also been carried on to a considerable extent on the Continent, particularly in Germany, but until quite recently only the total number and the number of liquefying bacteria have been estimated. In recent experiments the number of B. coli has also been recorded by the KI gelatine method. But while it is true that the total number alone is of only secondary importance, yet when an increase is due to sewage, a subsequent diminution probably indicates fairly accurately the amount of purification, and does not exaggerate it. For this reason it is worth while summarising the results obtained by Continental observers. Very different kinds of rivers have been observed varying in size from the Rhine at Cologne to mere brooks around Berlin.

Some official experiments done in 1890 by the Imperial Board of Health in Berlin showed that a small river, 24,710,400 gals. per 24 hours, receiving 1-30th its volume of sewage, left no traces of pollution 70km. below where the town of Rostock took its water supply. In this case very little fæcal matter entered the sewers.

In most instances the results are not so favourable, but the rivers have not been examined so far below the source of pollution. In the case of the Rhine, which has been investigated by several observers, the number of bacteria is permanently increased even 47·5km. below Cologne. The Isar, 33km. below Munich, still contains ten times the number of bacteria found just above Munich. The Limmat, receiving the sewage of Zürich, shows obvious contamination at 10·5km. from the town. In all of these cases the dilution is very considerably more than 1·15, the lowest limits required by Pettenkofer as the result of his experience. The most recent experiments have been made by the Government Committee appointed to investigate rivers from both chemical and biological standpoints. They have taken B. coli as a standard of pollution, and their conclusions will be found to coincide to a considerable extent with our own.

The following table (Table XXX.) shows very clearly the effect of pollution and the distance at which partial purification occurs.

TABLE XXX.

Results of Bacteriological Examination of various Rivers at and below large sources of Pollution.

THE SULPHURETTED HYDROGEN (H_2S) FORMING BACTERIA.

These were examined for by the ferro gelatine method on several occasions. In this medium these bacteria produce a rich dark brown colouration owing to the reduction of the iron, and are in consequence easily identified. We found that they were too irregularly distributed to serve as a test of pollution, although undoubtedly they were more numerous in cases of greater pollution. They are abundant where marsh gas is found.

THE SEWAGE FUNGUS.

The "sewage fungus" has been long recognised as an indicator of sewage contamination, but so far as we are aware no scientific description of it has as yet appeared in this country. In Germany, however, Mez and Schorler, with many others, have drawn especial attention to it, and we are now in a position to describe the chief species comprised under the title "sewage fungus." We, ourselves, have had many opportunities of studying it. We have been able to watch it for over one year in the Atcham Brook, which, as previously described, flows into the River Severn, for over two years in the River Alt flowing past the West Derby Sewage Farm; we have found it also at Dewsbury, Leeds, and Birmingham.

The "fungus" is a gelatinous, cottonwool-like, and wavy, white or reddish growth, which is found in shallow water, covering stones, lining drainpipes, or attached to water plants and débris; we have also found it in abundance in a urinal. It is an unmistakable indicator of sewage contamination, and quantities of it are often to be seen in the streams of sewage farms, and in the small brooks and drains highly charged with sewage which are found in the vicinity of houses and villages in the country. In company with the Commissioners we first saw it at Dewsbury in the mouth of the main effluent from the sewage farm. In this case the effluent was very bright, the tufts of the fungus were very long, and of a rusty colour, owing to a deposit of oxide of iron. This form of the fungus we subsequently identified as *Leptomitus lacteus.* Later at Birmingham we encountered great quantities of fungus in the stream receiving the various effluents from the sewage farm. So serious had the growth become at Birmingham that it had been found necessary to remove it by means of screens in order to prevent it from passing into the river where it would have produced a nuisance by setting up "secondary decomposition." That it was capable of doing so was amply demonstrated by that which had already been screened out, and which had been formed into a heap; decomposition had taken place when we saw it, the odour was very offensive, and the red colour of the oxide of iron, so characteristic of the living fungus, had given place to the black colour of the sulphide. In Germany, whilst inspecting one of the large sewage farms at Berlin, we observed "fungus" adhering to the débris in the small effluents, and we were informed that it had been a source of trouble to a bathing establishment situated in the river into which the collected effluents flowed. Subsequent inquiry by the authorities led to the conclusion that in this case no importance could be attached to its presence. There is no doubt, however, that owing to the gelatinous, bulky, and easily decomposable nature of the fungus, and the readiness with which it becomes detached, it may become one of the chief causes of "secondary decomposition" in small rivers and streams which receive sewage.

In the Atcham Brook, where we first found the "fungus" in connection with the Severn experiments, the growth was white, the tufts wavy and very gelatinous, and the brook almost completely choked by it. We could not at first account for its presence, for we were unable to see any source of contamination; bacteriological examination showed that the stream contained

large numbers of the B. coli, viz., 19,000 per cc., and therefore that it must be receiving sewage, and probably close at hand. This surmise proved correct, for we traced the stream to a connection with the sewer of the Atcham workhouse, a building which was hidden from sight from the river, the other feeder of the stream was apparently a pure water spring; the combination of clear running oxygenated water with sewage seems to be necessary for the development of the fungus. We did not observe the fungus passing into the Severn in any large quantity, nor do we think that under any circumstance it could lead to "secondary decomposition" in the river, the volume and velocity and the conditions of growth precluded this. In no part of the river, except in this stream, did we find the fungus, and this is not to be wondered at, considering the very great dilution which we have shown to take place in the sewage of Shrewsbury when it passes into the river. The variety of fungus found in the Atcham Brook proved to be *Sphaerotilus natans.* We have had the opportunity of studying this variety for a very long period in the River Alt, a small stream which receives the effluents from the West Derby Sewage Farm. In this river the growth forms characteristic tufts attached to the stones of the bed of the river. It is readily detached, and is liable to form accumulations and to assist secondary decomposition.

Classed under the heading of "sewage fungus" are certain distinct growths, the most highly organised of which is the Leptomitus, one of the Saprolegniaceæ, and, therefore, comparatively high in the scale of fungi. Next to it comes the Sphaerotilus, which may be placed amongst the more highly developed forms of bacteria. There are also various bacterial zooglea masses, which may assume a branching appearance and simulate a sewage fungus. One of the most interesting observations which we made during our investigations of these most useful fungi, was that in polluted brooks all the appearances of the typical fungus was sometimes caused by extensive growths of a protozoon, the *Carchesium lachmanni.* In the following brief description of the Leptomitus, Sphaerotilus, and Zooglea masses, it will be seen that each variety indicates a different degree of contamination.

*Leptomitus Lacteus (Agardh).**

This oomycete belongs to the family of the *Saprolegniaceae.* It is very soft, almost gelatinous, and may form white, rusty, or black masses. The white appearance is the natural colour of the growing filaments, but very soon this colour is replaced by a deposit on the hyphæ of oxide of iron. The rusty colour of the fungus is very characteristic, and is an indication that the stream in which it is found is well oxygenated If the oxygen is absorbed, as in the interior of masses of the growth, or in stagnant water, sulphide of iron is formed, and the fungus assumes a black colour, and undergoes putrefactive decomposition.

Microscopic examination shows that it consists of long branching filaments, which are constricted at regular intervals; the branches bud off below the constrictions, and each segment has a very characteristic refractile nucleus. Zoospores are formed in the terminal segments.

Sphaerotilus Natans.†

This organism belongs to the Schizomycetes, and may be readily confounded with the preceding. It forms quite as long wavy masses as does Leptomitus. It is, however, usually white and cotton wool-like when seen in the water. It is much more gelatinous than Leptomitus. On stones in shallow streams, or coating the sides of drain pipes, it forms low velvety or feather-like growths. Like leptomitus, it requires oxygen, and grows best in shallow water-courses, and where there is plenty of movement. Its presence indicates much greater pollution than does the former organism, and therefore it is of importance to be able to distinguish the two forms. In two cases where bacterial analyses were made of the water in which both forms of "fungus" were found, that in which leptomitus occurred contained at least less than 100 bacillus coli per c.c., whilst that in which sphaerotilus was found (viz., Atcham Brook) contained over 19,000 bacillus coli per c.c. With the introduction of the bacterial bed method of treatment, this organism has also made its appearance. In one case, where in the method of treatment the bacterial filter is warmed, we found that the sphaerotilus has made its appearance in large quantity, the conditions—circulation, aeration, presence of H_2S and warmth, being most favourable to its devolpment. It is, therefore, an organism which may cause blocking of aerobic contact beds, and from these may find its way into effluents.

Sphaerotilus has been long confounded with Beggiatoa. It is allied to the leptothrix forms. As the microscopic preparations show, it occurs in chains of short bacilli, or as long undivided filaments. It is, therefore, very much more minute than leptomitus. This is readily seen from the photomicrographs, which are equally magnified. The filaments and rods are surrounded with a gelatinous capsule.

A very great interest and importance may attach to this organism, if as Winogradsky has pointed out H_2S is essential to the life of Beggiatoa, and if this organism is the same as the Sphaerotilus. This fact would account for its presence in sewage. But, as pointed out above, it does not grow in crude sewage, although there is plenty of H_2S; this is owing to the absence of the oxygen, which is necessary in order to enable the protoplasm of the cells to take up the sulphur. Its presence, therefore, indicates an oxygenated sewage polluted water, and it is in this class of water in which we have ourselves always found it.

Zooglea Masses.

In crude undiluted sewage, a skin-like growth may form at the sides of the conduit in contact with the air, or at those points where crude sewage passes over a "lip." The growth, which has a coarse velvety appearance, consists of club-shaped zooglea masses of bacilli, and it seems probable that this bacterium, if not identical with Sphaerotilus, is closely allied to it. We found it in the very polluted drains entering the Severn.

From observations at Leeds in connection with the septic tank there appears strong evidence that the zooglea masses tend to form considerable quantities of sulphur from the dissolved sulphuretted hydrogen. Like the Sphaerotilus and Leptomitus they flourish best where the stream of sewage is most active and thinnest. This occurs in the case of the septic tanks at Leeds, where the effluent passes over the lip.

The Sphaerotilus natans can be regarded as peculiar to sewage contaminated water, we are not aware of its growing under any other circumstances. The Leptomitus thrives best in slightly polluted water, and there is no reason to think it may grow to even a slight extent in clean water. The Carchesium lachmanni is a protozoon which we have found in great masses under similar conditions to those of the Sphaerotilus. In our experience in no other conditions does it attain to such a luxuriant growth. Like therefore the sewage fungus it plays no unimportant part in sewage purification. Green algae may also develop to an enormous extent in sewage polluted water, when they do so they may be taken as sewage indicators just in the same way as Sphaerotilus, Leptomitus, and Carchesium. In polluted land drains we have observed great growths of the Flagellate, Euglena viridis, and most recently Dr. MacGowan has sent us a sample, which filled an effluent derived from a coke bed. Similarly Professor Letts has drawn attention to an Ulva in Belfast Loch associated with sewage contamination. Certain products of organic decomposition in the sewage appear to favour the growth of these chlorophyll forms as it does the non-chlorophyll group, and as will be seen in subsequent paragraphs there is evidence that green algae may play a most important and direct share in purifying organically polluted water. When large masses of these green algae perish they give rise, like the sewage fungi, to very objectionable smells.

THE ACTION OF THE PRODUCTS OF DECOMPOSITION DISSOLVED IN THE RIVER.

Diseases in cattle have been attributed to drinking sewage-contaminated river water, but there are no scientific data to show to what substances in the water the diseases were due. Even in the case of anthrax in cattle, the origin of which might be ascribed to drinking con-

† Other species have now been described, and these are now engaging our attention, as also methods for their isolation and study in pure cultures.

taminated river water, and where there is a possibility of infection from tannery refuse, and possibly even wool washings finding their way into the sewage, we are not aware that the bacillus has yet been demonstrated in sewage polluted water, although it has been found in a well supplying a flock of sheep.* Nor are we aware that any disease is in fact produced by the abnormal number of bacteria which pollution brings about. These are subjects, however, which require far more investigation than has as yet been given to them, before anything decisive can be said. With regard to the effects of the products of bacterial decomposition there can be little doubt that they act injuriously. We have shown in our oxidation experiments that bacteria when in large quantities absorb a great deal of oxygen, and produce a great deal of carbonic acid, and Spitta has recently calculated that 1 grm. of bacteria require 1·6 c.c. or ·00229 gr. of oxygen per hour. This absorption of oxygen and the evolution of not only CO_2, but of other gases such as H_2S, must act injuriously on fish life. Indeed König and Haselhoff have shown that carp and tench are injuriously affecter by 8 mgr. of H_2S per litre. In the case of the Severn we have shown that there exist large anaerobic deposits of sludge in certain places in the bed of the river passing through Shrewsbury, these give off H_2S, and will, therefore, affect the fish. The fish are also indirectly affected through the plant life in the river. The aquatic plants not only themselves serve for food for certain fishes, but they also harbour the lower forms of animal and vegetable life which help to support fish. We have observed that the green aquatic plants do not grow near the anaerobic decomposing mud, they require oxygen, and it is most probable also that they are as sensitive to dissolved sulphur and other gaseous compounds as are land plants. But this is again a subject which requires much further investigation. We do not wish to overstate the danger to fish life of pollution. Undecomposed sewage, or a non-putrescible effluent is probably innocuous, and it can also readily be understood that a small quantity of sewage entering a river may be rapidly decomposed by bacteria, and contribute largely to the support of the lowest forms of plant and vegetable life, and these in their turn to the higher forms. This does take place, and is comparable to the advantage on land of judicious manuring. We have, however, at Shrewsbury, described excessive pollution, a condition which, unfortunately, exists in many rivers, and which sooner or later produces changes which render higher animal and vegetable life impossible. In addition to bacterial poisons there are numerous instances of the poisoning of fish through mineral poisons discharged into sewage, finding their way into rivers.†

If our knowledge of the harmful effect of the dissolved products of bacteria is very slight, that of other dissolved products, such as toxines, is still less, and we take this opportunity of drawing the attention of the Royal Commissioners to the lack of information concerning the action of these poisonous substances in water which appear to play an important part in the reduction of animal and vegetable life in our polluted rivers. The few experiments which we have made appear to show that the effluent from a Whittaker bed is less toxic than that from a Dibdin bed, and certainly less than septic tank fluid or crude sewage.

CHEMICAL EXAMINATION OF THE RIVER SEVERN.

(Table XXIX.).

The analyses have been carried out by Mr. Frye, who will present his report on this part of the subject; but it might be of use here to make a short comparison between the bacteriological and chemical analyses, because they present some striking contrasts and parallels.

The albuminoid ammonia was high (up to 0·0197) at a time when the pollution as measured by B. coli (less than 30 per c.c.) was low. The total chlorine was highest (2·236) on an occasion when only 9 B. coli per c.c. were present and was low (1·106) when as many as 203 B coli per c.c. were found. Nor is the oxygen absorbed test any better, for on one day we find it at 0·290 with 19 B. coli per c.c., and lower down the river still at 0·290 with 250 B. coli per c.c. But the free ammonia corresponds very closely to the variations in number of B. coli, and on one occasion when the latter was high so far down as Uffington, so also was the free ammonia. The total chemical analysis therefore corresponds roughly to the "total number" of bacteriological analysis, and this we have seen to be more affected by seasonal and meteorological variations than the numbers of B. coli, and we can, therefore, not give it more importance than that attributed to "total numbers"; but the free ammonia apparently corresponds in the chemical to B. coli in the bacteriological analysis, and is, therefore, of considerable interest and importance.

Professor Ramsay's apparatus for the estimation of oxygen has been used three times. Once the river was found to be too muddy to read off the results; on the other two occasions the water was fully oxygenated above and below Shrewsbury; at the Foundry and Cherry Orchard Ferry there were 4 c.c. and 5 c.c. respectively. The pollution as tested in this fashion does not extend very far, although actually we know it to persist to much further down the river. The method has, however, not been given anything like sufficient trial.

THE SELF-PURIFICATION OF THE RIVER SEVERN.

Considerable attention has been paid to this subject upon the Continent by Pettenkofer, Schenk, Uffelmann, Schorler, König, Spitta, and most recently by the German Government. In the reports of the German observers special attention has been given to the classification of the flora and fauna of the polluted rivers, and to the share which they take in purification.

Our own experiments, on the other hand, have for the most part been confined to tracing out as accurately as possible what became of the pathogenic bacteria which found their way into the river. We have, however, also collected, in the time at our disposal, sufficient information upon the wider subject of the purification of rivers to make us entirely agree with the opinion expressed in the last German report that the enquiry is a vast one, and that a great deal of research is still required.

The deleterious action of sewage or of an impure effluent passing into a river arises, firstly, from the presence of pathogenic bacteria, *i.e.*, bacteria harmful to man and animals, and, secondly, from the presence of organic matter, which, undergoing decomposition, not only produces a nuisance and proves dangerous to the health of man, but also has a deleterious effect upon fish and many plants. The self-purification, therefore, of rivers may be considered under two heads—(1) the destruction of pathogenic bacteria, (2) the destruction of organic matter.

1.—DESTRUCTION OF INTESTINAL AND PATHOGENIC BACTERIA IN THE RIVER.

In the preceding pages we brought forward evidence to show that after a certain number of miles, the B. coli, which, for reasons stated elsewhere in this report, we regarded as an organism primarily of the intestine, rapidly diminished in numbers after passing in great quantities into the river with the sewage. It was shown that the B. coli either subsided to the bottom of the river or collected in the mud of the banks, and that there was no evidence of its multiplication, and, moreover, our observations upon the behaviour of the B. coli in the septic tanks and in earth filters corroborated this, and distinctly pointed to its destruction when removed from the alimentary tract. In substances like mud, teeming with putrefactive organisms, the available foodstuff is monopolised by the more hardy bacteria, and the putrefactive products which are formed act detrimentally (so our experiments seem to show) upon the pathogenic forms, but much further research is here again necessary.

The conditions for the multiplication of the B. coli group or of the B. typhosus in the flowing water are also unfavourable. We have no evidence that they multiply, and it has been shown by other observers that river water is unfavourable to their growth. But whilst the condition for the multiplication of these organisms is not met with in a river like the Severn, yet it always must be borne in mind that the B. coli group and the B. typhosus can remain alive for a considerable length of time, both in the mud and in the water.

On looking at the large chart (Chart I.) showing the relative proportion of the B. coli to the common bacteria, it will be seen that both are greatly increased by the inflow of sewage, and that after a certain dis-

*Ann. de l'Institut Pasteur, 1893, p. 286.

†The increasing use of carbolic acid as the common domestic water closet disinfectant, and the large use of disinfectants by municipal authorities, will probably in time produce effects in rivers.

tance has been traversed there is a fall, and the number of organisms is reduced to a figure almost similar to that before the sewage pollution. The explanation of the comparatively rapid disappearance from the river water of the putrefactive bacteria is probably as follows:—

In the case of the B. coli, and presumably also in the case of pathogenic bacteria generally, as we have pointed out, the temperature and environment are unfavourable to multiplication; on the other hand, the multiplication of the coarser bacteria is more dependent upon the food supply. To begin with, they are in an active state of multiplication in the crude sewage as it passes into the river. In this state they are free, and also attached in enormous numbers to the lumps of fat, fæces, and garbage generally. Together with this refuse they pass, as we have shown, to the banks, where the process of putrefaction is continued; quantities are deposited by sedimentation and settle to the bottom of the river, where also putrefaction is continued (as may be readily demonstrated both by bacteriological analyses and by the evolution of gases and putrefactive odours).

Sedimentation and side adhesion play, therefore, a most important part in ridding the flowing water of bacteria. That sedimentation is a powerful agent in reducing the number of bacteria in an effluent or sewage can be artificially demonstrated by adding a small quantity of a precipitant like alum; the organic matter is precipitated, and with it, to a large extent, the bacteria; but, as is well known, organic matter precipitated in this way or by lime or other chemicals is subject to a great amount of subsequent putrefaction, because the bacteria are not killed, but survive to continue their work in the sludge.

In addition to the solid organic matter in suspension in the sewage there is also a considerable amount in solution, which, like laboratory peptone broth, will serve as an admirable nutrient medium for the coarser bacteria. In the case of the Severn, the dilution which the sewage, and therefore which the organic matter in solution, undergoes is very considerable, and the food material is only sufficient for the comparatively small numbers of bacteria, shown in the various appended tables.

The chemical examination shows that after a few miles this food supply in the flowing stream becomes diminished, and at the same time the number of bacteria is greatly decreased. Without food there is no multiplication, and if there is no multiplication the bacteria, like other particles in suspension, undergo gradual sedimentation, and adhere to the sides and bottom of the river. Once incorporated in the mud they will continue to increase or die out according to the presence of suitable food supply and other conditions.

2.—THE DESTRUCTION OF THE ORGANIC MATTER IN THE RIVER.

What become of the impurities, both solid and in solution, carried into the River Severn in the sewage of Shrewsbury, or what would happen to similar impurities present in an improperly purified sewage effluent passing into a river, is a subject of great interest, and one upon which we have been enabled to make many observations. There is evidence to show that the coarser fish, rats, and birds, act as very effective scavengers. The larger animals which dwell in or by the river are the first to reduce much of the offal to excretory products, which in their turn are dealt with by lower forms of animal and vegetable life. By means of the cork experiments, and by numerous other observations we demonstrated that floating bodies tended to go to the banks, where the marginal flora acted as retaining strainers, and that owing to currents considerable accumulations occurred in numerous recesses along the banks. The solid floating matter once brought to the sides of the river becomes incorporated with the mud, and is decomposed by bacteria, just as in the case of manure or sewage on land or in contact beds. Aerobic fermentation takes place in the "wind and water line," viz., that portion of the banks sometimes submerged, sometimes exposed to the air, and reduces the organic matter to nitrates and to other food stuffs, which can be readily taken up by the green plants which flourish luxuriantly along the banks. Sedimentation also occurs, and especially in those parts of the river where the current is sluggish. We compared the action taking place in these sludge accumulations to that in the septic tank; anaerobic and H_2S forming bacteria develop, the mud is black, offensive gases are evolved, and there is no green submerged aquatic plants in their vicinity, because of the injurious products which are formed. Not all the solid matter in suspension collects in these effervescing anaerobic pools which are found in Shrewsbury, for a very large quantity must be carried by the velocity of the stream beyond the town, just as we have proved the B. coli to be carried to the shallow parts of the river. The shallow oxygenated river bed supports a luxuriant growth of the Water Ranunculus and Myriophyllum, the leaves of which are finely divided and adapted in a remarkable manner to strain the water floating through them, as can be seen by the débris and mud, which can be dislodged from them if they are disturbed. When the particles are arrested they are no doubt broken up by bacteria, and by the lower forms of animal life, and are reduced to substances which go to nourish the plants which retain them. The decomposition of the solid matter, whether proteid, fatty, or carbohydrate, is thus accomplished by the aerobic and anaerobic bacteria, which are present in the sewage and sludge, and the grit and insoluble mineral constituents gradually collect on the bed of the river and lead in time to silting. The bacteria are not alone in this destructive process, representatives of the lower forms of green algæ and the protozooa take a share.

In the microscopical examination which we have made of the bed of the Severn we have met representatives of both these groups, but not in such large quantities as has been described by Continental observers. We have found, however, as has already been pointed out in the previous section on "sewage growths," great quantities of motile Protophytes and Carchesium in places where pollution is very great.

The disappearance of soluble organic matter is a subject also of great interest, and about which evidence is accumulating although much further investigation is still needed. The purification is probably both chemical and biological. According to König and Grosse Bohle who have given considerable attention to self-purification sulphur can be oxidised independently of bacteria. Spitta in an extensive examination of the River Spree in the neighbourhood of Berlin, described recently in Volume 38 of the Archiv für Hygiene, carried out investigations showing the value of atmospheric oxygen and sunlight as oxidising agents. In this report, however, we are more immediately concerned with the evidence of the destruction of soluble organic matter through the agency of plant and animal life. The best evidence of the role of biological action is obtained in the small highly polluted drains which enter the Severn. Reference has been repeatdly made to the small brook at Atcham which receives the drainage of the Atcham workhouse before entering the Severn, and which is almost completely filled in places with long wavy gelatinous tufts of Sphaerotilus natans. All observers are agreed that this actively growing organism when in large masses, must take a very great share, if not the greatest share of any species of fungus which we know of, in oxidising the organic matter in solution in sewage. Its action upon sulphuretted hydrogen is also of the highest importance, if it is correct that H_2S is necessary to its growth. Unfortunately, owing to the excedingly bad descriptions of the more highly organised bacteria it is very difficult to determine the species with which those who have studied sulphur formation in bacteria have worked. It seems probable that Sphaerotilus and Beggiatoa have been confused together. The H_2S is largely derived from the decomposition of the numerous organic compounds containing sulphur, which are present in sewage. According to Hoppe-Seyler, however, it may also be produced by the decomposition of cellulose in the following manner. The cellulose is decomposed by bacteria into CH_4; the nascent marsh gas is reduced by calcium sulphate in solution; and H_2S is formed thus:—

$$CH_4 + CaSO_4 = CaCO_3 + H_2S + H_2O.$$

The researches of Winogradsky upon certain bacteria, amongst which further researches may place Sphaerotilus, show that the cells take up the dissolved H_2S, oxidise it, and produce water and free sulphur, and thus render inert a most injurious gas. It will be readily understood how very necessary oxygen is to the growth of these remarkable fungi, they can only accomplish their useful work in sewage when supplied with oxygen. The disadvantage of Sphaerotilus arises from its liability

when formed in large masses, to become detached and perish and to give rise to objectionable odours; therefore if its growth is encouraged care must be taken to prevent it entering streams. Leptomitus lacteus and Carchesium and numerous protozoa no doubt all take a share in getting rid of soluble organic matter. Recently considerable attention has been given to the share which the lower chlorophyll containing forms take in purification. It is not uncommon to find small land drains, especially those on sewage farms, or which receive farmhouse refuse, filled with a green growth for the most part composed of actively motile green cells, and comprising varieties of Euglena and Protococcus. According to Bokorny, König, and Grosse Bohle, these very low green forms can take up their nitrogen and CO_2 better from organic than from inorganic materials alone, and consequently they take a very important share in self-purification. If this is so they will also require not only oxygen as Sphaerotilus does, but also sunlight, and therefore, in contrast to the sewage fungi, they will perform the work best in sunlight. Because of these two, chlorophyll and non-chlorophyll containing groups, the purification of sewage can be carried on throughout the year.

The process of self-purification as briefly sketched above has begun to attract great attention, because in the various biological processes of sewage purification, now largely made use of, a similar purification is brought about by Sphaerotilus, green flagellata, protozoa, and bacteria of all kinds, but it is also evident that much further research is necessary to throw light upon this most interesting and practical subject.

NOTE UPON THE FLORA OF THE RIVER SEVERN AND THE SHARE IT TAKES IN PURIFICATION.

As the relationship of plant life to the purification of our streams is a matter of practical interest, we have made a survey of the plants growing in the river and on the banks, particularly with a view of ascertaining what share they took in cleansing the river.

Early summer, when the river is low, is particularly suited to the study of the flora of the river, and our own observations more particularly apply to the month of June, when the water ranunculus covers extensive reaches of the river with its white flowers.

We have already referred to the "wind and water line," a zone along the banks which is continually kept moist by the slight fluctuations of rising and falling of the stream throughout the day, by the action of the wind in producing waves on the surface of the water, and by capillary attraction. The zone is best seen in summer time, when the height of the river is not subject to extensive variations. In the case of the Severn it is for the most part free from vegetation, and consists of the exposed mud of the bank. The favourable conditions of moisture and food supply, owing to the tendency of organic material to collect to the banks, conduce to bacterial activity, and we have already compared the action which takes place in this zone to that which occurs in a contact bed or in irrigated land. It is also the zone which becomes covered with euglena, oscillatoricæ, closterium, or other protophytes if the water is polluted and the mud offensive. We have found green or blue-green scum on the mud of this zone only in the small polluted streams which enter the Severn, and here and there along the banks of the river itself as it flows through the town, usually after the discharge of a sewer. The polluted mud also harbours much animal life, Nais being especially abundant. It has been recorded that this small worm has reddened the offensive mud of the Thames, and we have ourselves seen masses of it blocking drains; it is also abundant in Dibdin effluents, and swarms may occur on Leptomitus and Sphaerotilus.

The permanently submerged banks support, in the deeper parts, Potamogeton perfoliatus, Potamogeton natans, Zostera, Myriophyllum verticillatum, and Ranunculus aquatica, and in the shallower parts the Sedges, Alisma, water Grasses, and Willows. Close in to the banks the water is sluggish and the growth of pond weeds is favoured; more externally there is often a zone of Myriophyllum; and still more externally, and immediately in contact with the flowing current, there is usually an abundant growth of the water Ranunculus This essentially aquatic flora is more abundant both above and below Shrewsbury than in the town of Shrewsbury, where the conditions of growth are no doubt less favourable. We have pointed out that the banks are often composed of refuse, and in places the mud is septic, or e banks are often washed by concentrated sewage. The available oxygen in the river is therefore much less, and in addition there are no doubt dissolved products of decomposition which are as inimical to plant life in water as certain gases are even in the most minute quantities to terrestial plants. In many parts of the town also the banks are too steep, and do not allow of sufficient foothold for submerged plants. Whilst for the most part plant life is not so abundant in the town, attention will shortly be directed to an exception which occurs at both bridges crossing the river.

The bed of the river from the asylum, two miles above Shrewsbury, to Cressage, 18 miles further down, supports an immense growth of water ranunculus. This weed grows best on a stony bottom, where the current is swift, and where the water is comparatively shallow. In the low state of the river in June, when we made our last survey, we found very little growth in depths of more than four feet, and in winter time this would mean that the plant was submerged to the extent of several feet. The plant forms wavy tufts 6 to 10 feet in length, which are composed of finely branching stems and leaves. The tufts form huge bundles which float in the water, and send to the surface the flowering stems. Everywhere where the river is shallow, and the stream swift, a complete barrier stretches from bank to bank. These barriers occur between the asylum and the waterworks, and below Shrewsbury at Uffington, Atcham, Wroxeter (Roman Ford), and above Cressage. In Shrewsbury itself an extensive growth extends across the river just below Welsh Bridge, and also across the river a short distance above English Bridge, both places where the river becomes very shallow and almost unnavigable, and the current is very swift; above them the river is deep and sluggish. The growth immediately above English Bridge is on a ledge which forms a veritable lip to the very deep pool which we have previously described. The services which these aquatic plants render a polluted river are very great, as after passing through such a barrier, the water is perceptibly brighter and cleaner, and if evidence is wanted of the amount of suspended matter which they filter out, it is only necessary to vigorously disturb a patch in order to give the water the muddy appearance which it has in flood time. The scum which is inseparable from a dirty river is likewise held back, and in certain places accumulates in large quantities. The fringe of Potamogeton and Myriophyllum close to the banks also acts as a most effective filter. The thread-like Conferva grows in immense masses in the meshes of these floating aquatic plants, and increases to a great extent their filtering action.

It is well known that aquatic plants give off great quantities of oxygen in the presence of sunlight, and the quantity produced by the enormous masses of the water ranunculus in the River Severn must be very large. This oxygen formation will most probably materially assist to neutralise the harmful, fermentation which takes place in the more highly polluted parts of the river, both by oxidising organic material and by helping to support those minute forms of animal and vegetable life which destroy organic matter. Microscopical examination of the matter adhering to the aquatic plants reveals the presence of numerous protophytes, protozoa, and bacteria; all of which no doubt take a share in getting rid of the impurities held up by the meshes of the more highly organised plants.

In the bays along the river with their more stagnant water an excellent picture is sometimes afforded of the zones of aquatic plants from bank to mid-stream. There is a bay at Uffington which receives the drainage from a few cottages. Upon the exposed mud, oscillatoriæ and euglena flourish; in the adjacent shallow water there is an abundant growth of conferva; further out the bay is filled with potamogeton perfoliatus and myriophyllum; and most externally, and therefore in contact with the swifter current, we find quantities of the water ranunculus.

It is truly a remarkable feature, and a very fortunate one, that in summer time, when the dilution is much less, and when putrefaction is much more active, the harmful effects of bacterial activity appear to be so soon neutralised. The beneficial effect of the growth of ranunculus on the lip of the deep stagnant pool above English bridge is comparable to the good effects of growth of sphaerotilus in shallow and more highly polluted streams, or of the zooglea masses of bacteria on the lips of the septic tanks at Leeds. But it must not be forgotten that we found the B. coli in larger numbers in low states of the river, so that some particles evidently escape the filtering action of the green weeds.

In winter, when the stream is swollen, and when the volume of water available for the dilution of sewage is very much greater than in summer, the filtering action of the aquatic weeds is very much less. The diluted sewage is carried down the river to a greater distance than in summer, and consequently the possibilities of infection in winter are probably as great as in summer. The banks are to a great extent submerged, with the result that the willows which fringe each side of the river are also partly under water. In this condition their delicate elastic branches take the place of the aquatic plants, and form most efficient strainers of the larger debris which floats in the river. That they have been efficient strainers in the wet season is demonstrated by the large amount of material of all kinds left adhering to them to rot when the river goes down.

CONCLUSIONS.

1. That the B. coli is a most reliable test of pollution.

2. That the B coli is normally absent in 1.c.c. quantities of water taken from the Vyrnwy watershed of the River Severn.

3. That when the B. coli is present in a small stream, contamination from houses can be traced.

4. That small land drains are comparatively free from B. coli.

5. That the small streams running into the Severn often contain considerable quantities of the B. coli due to contamination from proximity to houses.

6. That the sewage of Shrewsbury causes a very great increase in the number of B. coli in the river, and that sixteen miles lower down the effect of pollution can still be detected by the number of B. coli present.

7. That there is no evidence of the multiplication of the B. coli in the river water.

8. That the B. coli is present in considerable numbers in the mud of the Severn in the polluted area, and that this mud may be the means of keeping up and extending pollution, but that there is no evidence of the multiplication of the B. coli in the mud.

9. That there is comparison between total numbers of bacteria and the B. coli, but the relative proportion of the numbers of the latter to the former is small.

10. That differences occur between the number of B. coli in superficial and deep samples, and samples taken near the banks and in stagnant bays, and that therefore cross section samples should always be taken.

11. That sedimentation and side adhesion to the banks of the solids in suspension take place, and that at places in the bed of the river anaerobic fermentation occurs, whilst along the banks, especially in the wind and water line, aerobic bacteria actively help to destroy the organic matter.

12. That certain places in the river are very deep, and that these act as catch pits, that the stream in these places is sluggish, and that sedimentation is favoured.

13. That in the destruction of organic matter, whether solid or in solution, whilst the bacteria take the greatest share, help is also rendered by the protozoa and higher forms of animal life, by the sewage fungi, the chloropyll containing protophytes, and the river plants.

14. That the Sphaerotilus natans is a test of sewage pollution, and that it is a purifier of sewage.

15. That there is no evidence to show that pathogenic bacteria multiply in either the water or mud of the river.

16. That seasonal variations in the number of bacteria occur, but taking the B. coli as the test for pollution that the number of this organism is dependent upon the numbers present in the sewage entering the river, and that when the river is swollen and muddy the number is small owing to increased dilution, and that when the river is low the number is large owing to the lesser degree of dilution which the sewage undergoes when it enters the river.

17. That the effect of dilution of the river upon the sewage of Shrewsbury is most marked. That the average maximum number of B. coli in the river is only 600, per c.c. which is much less than in an average Dibdin effluent, whilst a short distance below pollution the number decreases very considerably.

18. That there is a relationship between chemical and biological analyses.

19. That the River Severn is a good example of a river which it would be difficult to class either as a potable or non-potable stream. It is true that the inhabitants of Shrewsbury consider it as non-potable, for they do not drink the water; but they use it for washing purposes, and consequently there is always a liability for, say, milk to become contaminated by being kept in a can which was washed with the river water. This liability is increased by the fact that the river is practically used as a tidal river, receiving as it does the whole of the untreated sewage of the town. Again, the river in close proximity to the town is used largely for watering cattle. Cattle may therefore contract disease from the water, and such disease may be communicated to human beings.

The river is also used for fishing, and has a recreative and ornamental value.

For these reasons we consider that it is as worthy of protection from pollution as any so-called potable river.

That whilst it would be onerous to expect absolute sterility in any effluent running into such a stream unless some simple method of sterilisation was discovered, yet a certain degree of bacterial purity, as shown by the B. coli test, might be insisted upon in addition to the chemical tests, for it would indicate the extent to which the intestinal bacteria were reduced by the method of sewage treatment employed.

20. That what has been described in this report upon the effects of allowing crude sewage to enter the River Severn is also applicable to biological effluents. Crude sewage is an example of the worst form of pollution, the effluents from biological methods of treatment examples of a lesser degree of contamination, because the solids in suspension in the latter are far less in amount and are in a fine state of division, and the number of the B. coli is smaller.

Shrewsbury with 29,000 inhabitants, and turning crude sewage into the Severn, causes an average pollution of 600 B. coli communis per c.c. (at the point of maximum pollution), and this is felt 16 miles lower down. But if a large town like Leeds were similarly situated, and the sewage were purified by contact beds so as to contain 10,000 B. coli communis per c.c., the pollution would still be about 1,000 B. coli communis per c.c., and if 600 B. coli communis are felt for 16 miles, 1,000 would be felt still further down. Consequently, in spite of the artificial purification, such a river would be in a worse condition than the Severn at Shrewsbury, which is admittedly bad. It follows that the purification thus attained would be insufficient, and that some further treatment would still be necessary.

Therefore a bacteriological examination of sewage effluents is necessary so as to ascertain whether the river can deal effectually with the sewage of its town.

R. BOYCE.

January, 1902.

TABLE I.

Bacteriological Examination of the River Severn above Asylum Outfall.

	Cound Brook	880	1	Absent	5
	Above Cound	2,310	22	Absent	3
	Cressage	2,490	46	Absent	5

The river, clean at the Waterworks soon became dirty in the town, particularly below the railway bridge, and remained so till near Uffington. Except single houses, no evidence of pollution was seen. In the town itself no fæcal matter was observed in the river, but near Pineapple Farm and below, at about 10·37 and 10·55 respectively, the boat passed through zones containing considerable fæcal matter. Height at Cherry Orchard Ferry, 3 ft. 3 in.

TABLE XV.

Bacteriological Examination of River Severn at Shrewsbury and Below.

Date.	Place.	Number of Bacteria per c.c.	B. Coli Communis per c.c.	B. Enteritidis Sporogenes per c.c.	Thermophiles per c.c.
30 Mar. 1900	Above Asylum	900	2	Absent	5
	Fifty yards below Asylum right bank	3,700	677	Present	3
	Above Waterworks	1,230	87	Present	5
	Bed of River at Waterworks	- - -	167	Absent	0 over.

	Bed above Welsh Bridge	- - -	1,450 per grm.	Present (in 0·5 c.c.)	ca. 100
	Ferry I.	3,000	130	Absent	9
	English Bridge	6,400	310	Present (in 0·1 c.c.)	12
	Ferry III.	3,900	203	Absent (in 0·5 c.c.)	10
	Municipal Boundary	4,700	250	Present	Cloud.
	Above Uffington	2,350	117	Present	11
		320	4	Absent	0
	Land drain, left bank	110	Absent	Absent	0
	Land drain, Burtons	965	Absent	Absent	12
	Atcham	1,650	11	Present	7
	Below Atcham	—	—	—	—
	Sewer of Atcham Workhouse	255,500	19,440	Present	40
	Wroxeter	1,260	6	Present	13
	Land drain, Coton's	110	Absent	Absent	0
	Land drain, right bank, Lower Cound Farm	610	Absent	Absent	5
	Above Cound	3,860	9	Absent	4
	Below Cound	2,720	15	Absent	6
	Cressage	- - -	15	Absent	10

The river a little higher than before. It looked somewhat dirtier everywhere, and although fairly clear above the Asylum outfall, below this solid fæcal matter and paper could be recognised right down to the intake of the Municipal Waterworks. Throughout the town fæcal matter, &c., could be observed, but the river is particularly dirty just beyond the Footbridge. Zones of sewage were met with as far as Monksmoor, and paper was seen even some distance below Atcham. Height at Cherry Orchard Ferry, 3ft. 5in.

TABLE XVI.

BACTERIOLOGICAL Examination of RIVER SEVERN at SHREWSBURY and Below.

Date.	Time.	Place.	Number of Bacteria per c.c.	B. Coli Communis per c.c.	B. Enteritidis Sporogenes per c.c.	Thermophiles per c.c.
12 April 1900	8.45 a.m.	WATER				
		Above Asylum outfall	390	1	Absent	2
		200 yards below, right bank	2,500	1,130	Absent	3
		200 yards below, left bank	365	Absent in 1 c.c.	Absent	Spreading.
		400 yards below, left bank (Stagnant Bay).	1,400	100	Absent	—
		Above Waterworks	610	16	Absent	3
		At Waterworks	430	34	Absent	3
		Ferry I.	1,400	93	Absent	2
		English Bridge	5,200	573	Absent	4
		Bay below Railway Bridge	9,000	173	Absent	13
		Ferry III.	2,770	170	Absent	3
		Ditch at Fever Hospital	1,950	6	—	1
		Uffington	3,400	115	Absent	3

		Land drain just above Railway Bridge II.	1,160	73	Absent	—
		Atcham	2,470	29	Absent	22
		Drain in Atcham	14,250	160	Absent	3
		Atcham Workhouse sewer	320,000	11,080	Present (in 0·1 c.c.)	120
		Above Cound	3,550	44 ?	Present	1
		Drain, Cound Inn	3,570	Doubtful, probably absent.	Absent	—
		Below Cound Inn	3,150	15	Absent	1
	3.40 p.m.	Cressage	3,100	48	Absent	4

The river was higher than on March 30th, and the current considerably more rapid. As a whole more muddy, but not so obviously sewage polluted. No fæcal matter seen below the town, nor very far below Asylum sewer. Below Atcham a sewer containing a luxuriant growth of sphaerotilus was discovered.

	Uffington, deep	193,400	269	—	—
	Drinking Water, Shrewsbury	100	Absent	Absent	—

* Numbers probably much too high.

The river was rather low. Mr. Kershaw's measurement gave a total of 112,008,000 gallons per 24 hours. Many of the sewer openings were only just under water, and the turbid stream issuing from them could be traced some distance. Many yellow corks (thrown in 17th May) were seen at various points along the whole course. Height at Cherry Orchard Ferry, 1 ft. 8 in.
